The research leading to the present invention was funded in part by grants from the National Institute of Health and the Rockefeller Foundation.

30 BACKGROUND OF THE INVENTION

The present invention is generally directed to materials and associated methods for the analysis and treatment of the effects and corresponding operation of invasive stimuli such as infection upon animal hosts, and in particular, is concerned with the identification of materials which may participate in the host response to such invasive stimuli.

35 Several common physiological and biochemical derangements have been observed in various mammalian hosts responding to a variety of invasive stimuli such as bacterial, viral or protozoal infection; tumors; or endotoxemia; as well as in idiopathic states. For example, these responses include fever, leukocytosis, hyperlipidemia, reduced food intake (anorexia), reduced activity, wasting (cachexia), and other modifications in muscle, white blood cell and liver metabolism. In particular, recent studies aimed at elucidating the biochemical mechanisms of cachexia in rabbits infected with *Trypanosoma brucei* noted that animals with a minimal parasite burden became moribund and exhibited

40 an extreme hypertriglyceridemia, with a marked elevation of plasma very low density lipoprotein (VLDL). See C.A. Rouser and A. Cerami, MOL. BIOCHEM. PARASITOL. 1:31-38 (1980). The hypertriglyceridemic state was remarkable in view of the severe wasting diathesis that accompanied this experimental infection. The elevation of plasma VLDL was shown to result from a clearing defect, caused by a loss of peripheral tissue lipoprotein lipase (LPL) activity.

45 Reduced LPL activity has been observed by others, and it has been noted that this condition has existed when the human body was in shock. See E. B. Man, et al., "The Lipids of Serum and Liver in Patients with Hepatic Diseases", CLIN. INVEST. 24 at 623, et seq. (1945); See also John I. Gallin, et al., "Serum Lipids in Infection", N. ENGL. J. MED. 281 at 1081-1086 (November 13, 1969); D. Farstchi, et al., "Effects of Three Bacterial Infections on Serum Lipids of Rabbits", J. BACTERIOL. 95 at 1615, et seq. (1968); S.E. Grossberg, et al., "Hyperlipaemia Following Viral Infection in the Chicken Embryo: A New Syndrome", NATURE (London) 208 at 954, et seq. (1965); Robert L. Hirsch, et al., "Hyperlipidemia, Fatty Liver and Bromsulphophthalein Retention in Rabbits Injected Intravenously with Bacterial Endotoxin", J. LIPID. RES. 5 at 563-568 (1964); and Osamu Sakaguchi, et al., "Alterations of Lipid Metabolism in Mice Injected With Endotoxins", MICROBIOL. IMMUNOL. 23 (2) at 71-85 (1979); R.F. Kampschmidt, "The Activity of Partially Purified Leukocytic Endogenous Mediator in Endotoxin Resistant C3H/HeJ Mice", J. LAB. CLIN. MED. 95 at 616, et seq. (1980); and Ralph F. Kampschmidt, "Leukocytic Endogenous Mediator", J. RET. SOC. 23 (4) at 287-297 (1978).

55 Additionally, publications are known by the Applicants that discuss the identification and existence of "mediators" that appear to be involved in the host response to infection; and in particular, the following articles, the texts of which are incorporated herein by reference, are listed: Sipe, J.D., et al., J. EXP. MED., 150:597-606 (1979); and Barney, C.

C., et al., LIPTON, J.M. (Ed.), FEVER: INTERNATIONAL SYMPOSIUM, Dallas, Texas, April 11-12, 1979 XII + 263P. Raven Press: New York, Illus. ISBN 0-89004-451-1 (08877), 0 (0), pp.111-122 (1980); and Dinarello, C.A., "Human Leukocytic Pyrogen: Purification and Development of a Radioimmunoassay", PROC. NATL. ACAD. SCI. USA, 74(10) at 4624-4627 (October, 1977). All of the factors identified and investigated by each of the authors in the above noted articles and the articles authored or co-authored by Kampschmidt have been determined to comprise a single grouping of factors which has been identified as interleukin-1 (IL-1). This determination has been documented in an article by Charles A. Dinarello, published in REVIEWS OF INFECTIOUS DISEASES, at Volume 6, No. 1 (January-February, 1984).

A similar deficiency of LPL activity was noted by Applicants in C3H/HeN mice after administration of Escherichia coli lipopolysaccharide (LPS). In contrast, the loss of LPL activity was not demonstrable in C3H/HeJ mice, which are genetically resistant to LPS. This resistance to endotoxin-induced LPL deficiency could be circumvented by the administration of serum obtained from endotoxin-sensitive animals that had been injected with LPS two hours previously. Similarly, resistance could be overcome by injecting conditioned medium from endotoxin-stimulated thioglycollate-elicited peritoneal macrophages obtained from sensitive mice. These findings were set forth in full detail in Application Serial No. 414,098, now U.S. Patent No. 4,603,106.

The above work was prompted by the Applicants' belief that a "mediator" or "mediators" existed and were suspected to have a significant effect upon general metabolic activity of energy storage cells in the animal host. It was suspected that such "mediators" exerted a depressive effect upon the activity of certain anabolic enzymes, whose reduced activity was observed, for instance, where the host enters the condition known as shock, as in response to invasion. Resultingly, the relationship of the mediator produced by endotoxin-stimulated peritoneal mouse exudate cells, upon endotoxin-sensitive and endotoxin-insensitive mice alike, and the development through such investigation of a reagent for the measurement of anabolic enzyme activity was set forth in first filed abandoned application Serial No. 299,932.

Further investigation of this system was made in conjunction with the 3T3-L1 "preadipocyte" model system, and the corresponding development of methods and associated materials for the development of antibodies to the "mediator" and other diagnostic procedures was then set forth in application Serial No. 351,290. Thereafter, in subsequent application Serial No. 414,098, now U.S. Patent No. 4,603,106, the Applicants established that the mediator substance that they had derived from the endotoxin stimulation of macrophage cells exhibited the activities of suppressing the anabolic enzymes lipoprotein lipase, acetyl Coenzyme A Carboxylase and fatty acid synthetase, and further, inhibited the growth and differentiation of erythroid-committed cells.

Additional work set forth in articles (1) and (4) by Beutler et al., and Application Serial No. 766,852, has resulted in the discovery that the earlier identified mediator substance contained a further protein component which possesses a number of activities, which distinguished it from both the mediator substance and the other factors identified in the art and known as Interleukin 1 and Interleukin 2. Further work set forth in article (7) by Beutler et al. and Parent Application Serial No. 104,827, the disclosure of which is incorporated herein by reference, established the presence of an additional factor (MIP-1) in the mediator substance which demonstrates a distinguishable profile of activities.

Since that time, MIP-1 has been resolved into component peptides and the N-terminal sequences of two such peptides, now referred to as MIP-1 α and MIP-1 β , have been compared. Accordingly, the present application is directed to the newly discovered peptide isolates and the activities of MIP-1, and the applications both diagnostic and therapeutic to which these isolates may be put.

SUMMARY OF THE INVENTION

In accordance with the first aspect of the present invention, the inflammatory cytokine that is the newly discovered isolate of the mediator substance is disclosed, and comprises a protein that has been purified and is anionic under physiological conditions. The inflammatory cytokine of the present invention exhibits the ability to bind to heparin, even at high salt concentrations, to induce localized inflammation characterized by polymorphonuclear cell infiltration when administered subcutaneously and to induce *in vitro* polymorphonuclear cell chemokinesis. The present inflammatory cytokine however, lacks certain activities common to other factors that have been isolated from the mediator substance disclosed in U.S. Patent No. 4,603,106.

In particular, the present inflammatory cytokine lacks the ability to suppress the activity of the anabolic enzyme lipoprotein lipase (LPL), and is unable to cause the cytotoxicity of cachectin/TNF-sensitive L929 cells, to stimulate the blastogenesis of endotoxin-resistant C3H/HeJ thymocytes, or to induce the production of cachectin/TNF by primary thioglycollate-elicited mouse macrophage cells. These latter characteristics all absent from the present inflammatory cytokine are exhibited by the known factors cachectin/TNF and interleukin-1 (IL-1), and thereby distinguish the present inflammatory cytokine therefrom.

Of the affirmative activities exhibited, the ability to bind to heparin and to induce localized inflammation characterized by polymorphonuclear (PMN) cell infiltration appear most significant. Accordingly, while the exact role that the present isolate plays in the cascade of reactions to host invasion is as yet ill defined, its participation in the elicitation

of certain of the activities and conditions associated with mobilization against host invasion is clear. Accordingly, the inflammatory cytokine possesses the potential for use as a diagnostic tool to identify and perhaps differentiate between various stimuli whether invasive or idiopathic, by the activation of the present inflammatory cytokine that such stimuli may promote.

The present inflammatory cytokine was initially partially identified and characterized and found to contain certain polypeptide segments defining an apparent molecular weight of approximately 8,000 daltons as determined on polyacrylamide gel electrophoresis in the presence of sodium dodecyl sulphate (SDS-PAGE) with the tendency to form aggregates of high molecular weight greater than about 10^6 daltons in low salt buffers. In particular, the present inflammatory cytokine has been noted to form aggregates greater than 2×10^6 daltons as assessed by gel filtration. Accordingly, preliminary partial N-terminal amino acid consensus sequence data as depicted in FIGURE 3 herein, revealed at that time no significant homology with any previously described proteins. By known cDNA cloning techniques based upon the partial peptide sequences determined, full translated peptide sequences were achieved, which have been found to possess molecular weights of approximately 8 kilodaltons. MIP-1 has been shown to have a pI of approximately 4.6 by chromatofocusing.

Further properties of the present inflammatory cytokine include its ability to induce fever in rabbits, and to induce superoxide formation or a respiratory burst in human neutrophils in vitro. These properties are illustrated in the data presented herein.

The present invention is also directed to the resolution of purified native MIP-1 which migrates as a doublet on SDS-PAGE with nearly identical apparent component molecular weights of about 8000 daltons. Chromatography on hydroxylapatite in the presence of SDS successfully separated the two components. Partial N-terminal sequence analysis of each component revealed that the two proteins are very similar in their N-terminal sequence but differ in the presence and positions of certain amino acids. In particular, the protein corresponding to the lower molecular weight band on SDS-PAGE (now termed "MIP-1 α ") had the partial N-terminal amino acid sequence shown in FIGURE 14A herein, whereas the higher molecular weight band (termed "MIP-1 β ") yielded the N-terminal sequence shown in FIGURE 14B. cDNA's for both MIP-1 α and MIP-1 β have been cloned, allowing for the prediction of the complete amino acid sequence of each of the peptide components, which cDNA and mature amino acid sequences are depicted in FIGURES 10 and 15, respectively.

The cDNA for MIP-1 α predicts a mature protein of 69 amino acids in length with a predicted molecular mass of 7,889. There are no apparent sites for N-glycosylation. The cDNA for MIP-1 β predicts a mature protein also of 69 amino acids in length with a predicted molecular mass of 7,832 daltons. There is one potential N-glycosylation site (Asn-Pro-Ser) at positions 53 to 55.

As mentioned earlier, the present inflammatory cytokine may be prepared by the stimulation of animal cells with a material such as might accompany an invasive stimulus. In particular, a sample of macrophage cells which may be derived from a variety of sources may be incubated with a stimulator material such as endotoxin or trypanosomes, to produce the mediator substance disclosed in U.S. Patent No. 4,613,106. Such incubation may take place for a period of time of up to twenty hours, and exact time limits will vary with the particular cells selected for incubation.

Following such incubation, the medium may be appropriately treated as by centrifuging, to remove a supernatant containing the crude mediator substance. The mediator substance may then be further treated as by filtration or precipitation. Thereafter, the crude mediator substance may be subjected to a series of known isolation techniques, whereupon the inflammatory cytokine may be recovered. The present invention naturally contemplates alternate means for preparation of the inflammatory cytokine, including where applicable known genetic replicative techniques, and the invention is accordingly intended to cover such synthetic preparations within its scope.

As noted above, the present invention also includes the identification of the purified peptide components of the present cytokine that exhibit in combination the above noted activities and characteristics, that display the mature amino acid sequences set forth below and in FIGURES 10 and 15, as determined in mice.

As stated earlier, the foregoing sequence bears no striking similarity to any of the known mediator factors and accordingly establishes that the present inflammatory cytokine is distinguishable therefrom. The recent isolation of the above amino acid sequences and the development of the mRNA sequence have facilitated the reproduction of this cytokine by conventional recombinant genetic techniques.

The invention further includes methods for identifying idiopathic or invasive stimuli on the basis of their ability to induce the present inflammatory cytokine or the activities that it affects. In particular, such stimuli could be identified and detected by their ability to induce mediators which bind to heparin and induce localized inflammation with neutrophil infiltration and chemokinesis. In this method, macrophage cells derived for example, from the RAW 264.7 cell line could be inoculated with a number of known stimulator materials such as endotoxin, trypanosomes or the like, as a control, while parallel cellular samples could be inoculated with an extract of material from the presumed situs of the infective stimulus. All samples could thereafter be incubated in accordance with the methods described above, and thereafter subjected to the sequence of separation techniques also defined, whereupon testing of the resulting isolates derived from the control and unknown samples could be compared to determine whether the inflammatory cytokine, if any, developed is identical or even similar.

Alternatively, altered mRNA levels of the inflammatory cytokine could be detected by techniques used in the art that make use of cDNA sequences disclosed herein.

In similar fashion, an assay system for screening of potential drugs effective to either mimic or counteract the inflammatory cytokine may be prepared. In one instance, the test drug could be administered to a stimulated macrophage sample to determine its effect upon the production of the inflammatory cytokine. In an alternate procedure, the inflammatory cytokine may be introduced into a cellular test system in which the cytokine is known to be active, and the prospective drug may also be introduced to the same cell culture and the culture may thereafter be examined to observe any changes in the activity of the inflammatory cytokine in comparison with the addition of the prospective drug alone, or the effect of added quantities of the known inflammatory cytokine.

The present invention also relates to a method for determining the presence of stimulated, spontaneous, or idiopathic pathological states in mammals, by measuring the activity and presence of the inflammatory cytokine of the present invention. More particularly, the activity of the inflammatory cytokine may be followed directly by the assay techniques discussed later on, through the use of an appropriately labeled quantity of the cytokine. Alternately, the cytokine can be used to raise binding partners or antibodies that could in turn, be labeled and introduced into a medium such as serum, to test for the presence of inflammatory cytokine therein, and to thereby assess the state of the host from which the medium was drawn.

Thus, both the inflammatory cytokine and any antibodies that may be raised thereto, are capable of use in connection with various diagnostic techniques, including immunoassays, such as a radioimmunoassay, using for example, an antibody to the inflammatory cytokine that has been labeled by either radioactive addition, reduction with sodium borohydride, or radioiodination.

In an exemplary immunoassay, a control quantity of the inflammatory cytokine, its antibody, or the like may be prepared and labeled with an enzyme, a specific binding partner and/or a radioactive element, and may then be introduced into a blood sample of a mammal believed to be undergoing invasion. After the labeled material or its binding partner(s) has had an opportunity to react with sites within the sample, the resulting mass may be examined by known techniques, which may vary with the nature of the label attached.

In the instance where a radioactive label, such as the isotopes ^{14}C , ^{131}I , ^3H , ^{125}I and ^{35}S are used, known currently available counting procedures may be utilized. In the instance where the label is an enzyme, detection may be accomplished by any of the presently utilized colorimetric, spectrophotometric, fluorospectrophotometric or gasometric techniques known in the art.

The present invention includes an assay system which may be prepared in the form of a test kit for the quantitative analysis of the extent of the presence of the inflammatory cytokine. The system or test kit may comprise a labeled component prepared by one of the radioactive and/or enzymatic techniques discussed herein, coupling a label to the inflammatory cytokine; and one or more additional immunochemical reagents, at least one of which is a free or immo-

bilized ligand, capable either of binding with the labeled component, its binding partner, one of the components to be determined or their binding partner(s).

In a further embodiment, the present invention relates to the use of the inflammatory cytokine, antibodies to the inflammatory cytokine, or upon other agents or drugs determined to possess the same or an antagonistic activity in certain therapeutic methods. A first use is associated with the prevention of the manifestations of the activities of the inflammatory cytokine in mammals, such as inflammation and fever, and comprises administering either an antibody to the cytokine, an agent capable of modulating the production and/or activity of the cytokine, or an agent not an antibody to the cytokine that is capable of acting as an antagonist to the cytokine, either individually or in mixture with each other in an amount effective to prevent the development of those conditions in the host.

More specifically, the therapeutic uses generally referred to herein could include the use for the treatment of inflammation and fever by the administration of pharmaceutical compositions that may comprise effective quantities of antibodies to the inflammatory cytokine, or other equally effective drugs developed, for instance, by a drug screening assay prepared and used in accordance with a further aspect of the present invention. A variant embodiment of this therapeutic use could include initially detecting the presence and activity of the inflammatory cytokine and thereafter administering the appropriate pharmaceutical composition.

A second therapeutic use seeks to take advantage of the inflammatory activity of the cytokine and in particular, its ability to cause the movement and mobilization of neutrophils in response to invasive stimuli such as infection. Accordingly, the inflammatory cytokine may be prepared in a suitable formulation for administration to the situs of infection which for example, may develop where tissue trauma has occurred. In such instance, the inflammatory cytokine prepared in a sterile solution and delivered to the trauma or wound as part of an irrigation fluid or by direct dosage such as, in a pharmaceutical composition, the latter course of administration contemplating topical and parenteral routes. Naturally, the inflammatory cytokine may be used to raise equally effective agents or drugs by known methods that may then be formulated into pharmaceutical compositions suitable for administration in the same manner and for the same purpose as for the inflammatory cytokine itself.

Accordingly, it is a principal object of the present invention to provide an inflammatory cytokine in purified form that exhibits certain characteristics and activities associated with the host response to invasive stimuli in mammals.

It is a further object of the present invention to provide a method for detecting the presence of the inflammatory cytokine in mammals in which invasive, spontaneous, or idiopathic pathological states such as infection are suspected to be present.

It is a further object of the present invention to provide a method and associated assay system for screening substances such as drugs, agents and the like, potentially effective in either mimicking the activity or combating the adverse affects of the inflammatory cytokine in mammals.

It is a still further object of the present invention to provide a medical use for the treatment of mammals to control the amount or activity of the inflammatory cytokine, so as to alter the consequences of such presence or activity.

It is a still further object of the present invention to provide a medical use for the treatment of mammals to promote the amount or activity of the inflammatory cytokine, so as to treat or avert the adverse consequences of invasive, spontaneous or idiopathic pathological states.

It is a still further object of the present invention to provide pharmaceutical compositions for use in therapeutic methods which comprise or are based upon the inflammatory cytokines or their binding partner(s), or upon agents or drugs that control the production, or that mimic or antagonize the activities of the inflammatory cytokine.

Other objects and advantages will become apparent to those skilled in the art from a review of the ensuing description which proceeds with reference to the following illustrative drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

FIGURE 1 is a combined graphical and electrophoretic gel depiction of the preparation and recovery of the inflammatory cytokine from a supernatant of RAW 264.7 cells. Fractionation of the concentrated, diafiltrated supernatant from RAW 264.7 was performed on Mono Q. Two liters of supernatant (mediator substance) were concentrated twenty times and diafiltrated against six liters of 20mM Tris-HCl, pH 8.0. The concentrated supernatant was applied to Mono Q and eluted with a linear gradient of 0 to 1 M NaCl in the same buffer. MIP-1 (*) eluted slightly before cachectin/TNF (**) at approximately 0.37 M NaCl. The insert shows a 10-15% SDS-PAGE gel to which 50 µl from the indicated fractions have been applied.

FIGURE 2 is a combined graphical and electrophoretic gel depiction of further gel separation and purification of the present inflammatory cytokine. Peak MIP-1 containing fractions from Mono Q were concentrated to 200 µl and applied to a Superose 12 column equilibrated with 100 mM ammonium acetate. MIP-1 (*) eluted in the void volume, well separated from cachectin/TNF (**). The insert shows a 10-18% SDS-PAGE gel to which 50 µl aliquots from the indicated fractions have been applied. The dagger indicates purified MIP-1 used as a marker.

FIGURE 3 depicts a consensus partial amino acid sequence of the first 31 positions of the inflammatory cytokine

of the present invention. Residues in parentheses indicate positions at which "minor" residues were reproducibly obtained in different sequence runs on different batches of material.

FIGURE 4 is a combined graphical and electrophoretic gel depiction of the binding and elution of the inflammatory cytokine of the present invention to heparin. Two ml of 12-fold concentrated and diafiltrated LPS-stimulated RAW 264.7 supernatant were applied to a heparin-Sepharose column and eluted with a linear gradient of 0 to 2 M NaCl in 0.02 M Tris-HCl buffer, pH 7.8. Two major peaks were observed; MIP-1 (*) eluted in the second peak, corresponding to 0.6-0.75 M NaCl. The insert shows a 10-18% acrylamide gradient SDS-PAGE gel to which 50 μ l aliquots from the indicated fractions have been applied.

FIGURE 5 shows photomicrographs of C3H/HeJ footpads fixed 4 hours following subcutaneous injection of the inflammatory cytokine of the present invention with controls and comparative injections of cachectin/TNF. Tissues were fixed in buffered formalin and stained with hematoxylin-eosin. Magnification is 400X. Plate A - Sham injections reflecting normal histology. Plate B - 100 ng MIP-1: moderate infiltration of neutrophils and mast cells. Plate C - 100 ng cachectin/TNF: moderate infiltration of neutrophils. Plate D - 10^{-10} moles fMLP: extensive infiltration with some focal necrosis.

FIGURES 6 graphically depicts the results of tests for the induction of neutrophil chemokinesis by the inflammatory cytokine of the present invention. Data represent the mean percent of the control migratory response of five experiments. Values are presented as the percent increase in neutrophil migration relative to the Gey's basic salt solution negative control (0%) and the 10^{-6} M fMLP positive control (100%). * = concentrations of MIP-1 showing significant increases in the percent chemokinetic response versus GBSS alone ($p < 0.01$ by ANOVA).

FIGURE 7 is a graphical depiction of the results of tests for the ability of the inflammatory cytokine to stimulate H_2O_2 release by human neutrophils (PMN'S). Human PMN'S incubated in serum-coated microtest plate wells were treated at time 0 with PMA (100 ng/ml) (●), recombinant cachectin/TNF (10 ng/ml) (Δ), MIP-1 (1000 ng/ml) (o) or an equivalent volume of buffer alone (control) (\blacktriangle). H_2O_2 release was monitored over the next 4.5 hours (2 hours for cachectin/TNF). Values are means \pm SEM for triplicates in one of 4 similar experiments.

FIGURE 8A is a depiction of the cDNA-predicted mature amino acid sequence of MIP-1 α as initially recovered from murine cells.

FIGURE 8B is a depiction of the cDNA-predicted mature amino acid sequence of MIP-1 β as initially recovered from murine cells.

FIGURE 9 depicts 512-fold degeneracy probe pools used in the cDNA cloning of MIP-1 α . An asterisk below a base indicates a constant base change between the two-probe pools.

FIGURE 10 depicts the complete nucleotide sequence of a cDNA clone for MIP-1 α . The underlined sequence indicates the complementary sequence of the oligonucleotide used in primer extension experiments. The predicted translated molecular weight of the precursor peptide is 10,346. The mature peptide sequence, starting at position one, is 69 amino acids in length and has a predicted molecular weight of 7,889.

FIGURE 11 is an autoradiogram of a northern blot of total RNA from RAW 264.7 cells, a transformed murine macrophage cell line. The cells were stimulated with LPS at 2 μ g/ml in serum-free medium for 6 hours. Control cells were given serum-free medium with no added LPS for 6 hours. The total amount of RNA loaded in each lane is indicated on the figure.

FIGURE 12 is a depiction of a time-course study of RAW 264.7 mRNA induction by LPS. The time course is measured in hours. All three probes were plasmid cDNA clones labeled with α -[32 P] dCTP.

FIGURE 13 is a graphical depiction of the fractionation of MIP-1 into component peptides by SDS-hydroxylapatite chromatography. MIP-1 (500 μ g) was applied to SDS-hydroxylapatite and fractionated as described. 0.5 ml fractions were collected, analyzed by SDS-PAGE, and pooled as indicated by brackets (1 = MIP-1 α ; 2 = MIP-1 β).

FIGURE 14 depicts N-terminal amino acid sequences: (A) The N-terminal amino acid sequence of purified MIP-1 α ; (B) The N-terminal amino acid sequence of purified MIP-1 β , the residues underlined (2-8) were those used to construct an oligonucleotide probe pool; (C) The original N-terminal amino acid consensus sequence reported for purified native MIP-1. Amino acid residues corresponding to the minor residues are given in parenthesis.

FIGURE 15 depicts the complete nucleotide sequence of the cDNA clone for MIP-1 β . The predicted translated molecular weight is 10,169 daltons. The mature protein sequence, starting at position one, is 69 amino acids in length and has a predicted molecular weight of 7832 daltons.

FIGURE 16 is a graphical depiction of estimated local hydrophobicity along the length of MIP-1 α (---) and MIP-1 β (-) calculated by an adaptation of the algorithm of Hopp and Woods.

DETAILED DESCRIPTION

In its primary aspect, the present invention concerns the isolation and identification of a particular factor hereinafter referred to as inflammatory cytokine or macrophage inflammatory protein, MIP-1, that has been found to be present in or secreted by macrophages or macrophage cell lines that are stimulated by materials referred to herein as stimulator materials, that characteristically accompany an invasive stimulus, such as bacteria, viruses, certain tumors, protozoa

and other toxins such as endotoxin, or an idiopathic state. The present invention also pertains to the resolution of MIP-1 into its component peptides, MIP-1 α and MIP-1 β . As with the mediator substance disclosed in U.S. Patent No. 4,603,106, the present inflammatory cytokine, which has been determined to be a component of the former mediator substance, appears to be capable of causing certain conditions such as inflammation to develop in the tissues of a mammal, which reflect the reaction of a mammal in a stimulated or spontaneous pathological state.

In particular, the inflammatory cytokine appears to be capable of inducing localized inflammation when administered subcutaneously which inflammation is characterized by polymorphonuclear cell infiltration. Also, the cytokine causes *in vitro* polymorphonuclear cell chemokinesis, which conditions are reflective of the influence of a cytokine involved in mobilization by the mammalian host against an invasive stimulus. While the full and exact role played by the present inflammatory cytokine is unclear, it is theorized that the cytokine in conjunction with other factors previously identified and those yet to be elucidated, functions as part of a communication system between the immune system of the host and other body tissues and organs.

The ability of the present inflammatory cytokine to bind to heparin gave rise to the consideration that the cytokine might correspond to certain heparin-binding growth factors such as FGF or PDGF. However, data indicating that the inflammatory cytokine is not mitogenic for smooth muscle cells suggests a distinction from these known growth factors. Accordingly, what is certain at this time, is that the cytokine of the present invention participates in the development of the inflammatory response that is known to be a part of host responses such as to invasion.

As indicated earlier, the present inflammatory cytokine has been confirmed to comprise a protein that possesses an isoelectric point (pI) of approximately 4.6. The inflammatory cytokine can be isolated as a doublet with nearly identical subunit molecular weights of approximately 8,000 daltons and may form multimers of various molecular weights up to and exceeding 2×10^6 daltons as assessed by the results of the investigations that led to its isolation, which are set forth in the Example below. These investigations likewise identified the N-terminal peptide sequences, and the full sequence thereafter developed by known genetic replicative techniques confirm that the specific peptide sequences of the present inflammatory cytokine differ from that of other known mediator factors. Accordingly, both structural and functional distinctions between the present inflammatory cytokine and the known mediator factors of the prior art exists as is confirmed by the data set forth in the Example.

More particularly, the inflammatory cytokine of the present invention possesses certain other characteristics in conjunction with those outlined above, in that it is capable of binding to heparin at high salt concentrations, e.g. approximately 0.7 M. A further characteristic of the present inflammatory cytokine is that it is anionic under physiological conditions. The cytokine is also distinctive in those activities that it lacks, such as the inability to suppress the anabolic enzyme lipoprotein lipase (LPL), to cause the cytotoxicity of cachectin/TNF-sensitive L929 cells, stimulate the blastogenesis of endotoxin-resistant C3H/HeJ thymocytes or to induce the production of cachectin/TNF by primary thioglycollate-elicited mouse macrophage cells. All of these latter activities are those shared by the other known macrophage-derived mediator factors whose general characteristics and activities have identified them as participants in the host response to invasion. This accordingly distinguishes the present inflammatory cytokine from those known factors and confirms in conjunction with the cDNA and protein sequencing data presented herein, that the present inflammatory cytokine is indeed distinct from the other macrophage-derived mediator factors.

The inflammatory cytokine in accordance with the present invention was isolated and analyzed in mice as set forth in the Example herein. Further work of cloning and sequencing the cDNA of the message for the distinct polypeptides of the inflammatory cytokine performed after the completion of the experiments set forth in the Example has resulted in the elucidation of the complete sequence of the peptides MIP-1 α and MIP-1 β , and their sequences are presented herein in FIGURES 10 and 15, respectively. It has therefore been determined that the purified inflammatory protein is defined by two sequences each of 69 amino acids.

A cDNA library was prepared from endotoxin-stimulated RAW 264.7 cells and was screened using two synthetic oligonucleotide pools based on the "major" partial N-terminal amino acid sequence of MIP-1. The cDNA so cloned is shown to correspond to the peptide chain now known as MIP-1 α . The cDNA for MIP-1 β was cloned using a similar strategy, although here the oligonucleotide pool used was derived from a portion of the molecule in which three of the seven amino acid residues are different from the corresponding residues in MIP-1 α .

The cDNA for MIP-1 α predicts a mature protein of 69 amino acids in length with a predicted molecular mass of 7,889. There are no apparent sites for N-glycosylation. The cDNA for MIP-1 β predicts a mature protein also 69 amino acids in length with a predicted molecular mass of 7,832 daltons in which there is one potential N-glycosylation site (Asn-Pro-Ser) at position 53-55. As MIP-1 β migrates on SDS-PAGE as a slightly larger molecule than MIP-1 α , it is possible that it is glycosylated. It is known that proline at position X in the Asn-X-Ser, Thr signal for N-linked glycosylation results in impaired or absent glycosylation at that site. This may account for the relatively small difference in molecular mass between MIP-1 α and MIP-1 β should the latter be glycosylated.

Experiments are now under way to express the recombinant form of this disclosed protein. Human inflammatory cytokine MIP-1 is presumably similar to mouse MIP-1, since the mouse MIP-1 has an effect upon human neutrophils. As disclosed herein, this activity of the inflammatory cytokine may be harnessed by administering the inflammatory

cytokine to the situs of tissue infection to promote the delivery of neutrophils to that location.

The genetic replication of the inflammatory cytokine involves many of the general principles of recombinant technology that are well known in the art, and accordingly a detailed presentation of such techniques is not deemed to be necessary and is not presented herein. The present invention, however, contemplates the preparation of the present inflammatory cytokine, and in particular the material having the amino acid sequences set forth in FIGURES 10 and 15, by known recombinant techniques. The preparation of the inflammatory cytokine was discussed in brief earlier herein, and is confirmed to be capable in one aspect of proceeding by the initiation of the incubation of any of a variety of cells with stimulator materials such as from invasive stimuli. In particular, the cell line RAW 264.7 may be utilized to initiate the production of the mediator substance from which the inflammatory cytokine may be isolated. The murine macrophage cell line RAW 264.7 has facilitated the isolation of the inflammatory cytokine in quantities large enough to permit analysis and purification. Naturally, other cell lines or other sources for the development of either the material from which the inflammatory cytokine is thereafter isolated (mediator substance), or the inflammatory cytokine or its constituent peptides, are contemplated herein and the present invention is accordingly not limited. Thus, alternate means such as by genetic replication are contemplated herein in accordance with the present invention.

As discussed earlier, the inflammatory cytokine, its constituent peptides, their binding partner(s) or other ligands or agents exhibiting either mimicry or antagonism to the cytokine or control over its production, may be prepared in pharmaceutical compositions, with a suitable carrier and at a strength effective for administration by various means to a patient having a tissue infection or other pathological derangement, for the treatment thereof. A variety of administrative techniques may be utilized, among them topical applications as in ointments or on surgical and other topical appliances such as, surgical sponges, bandages, gauze pads, and the like. Also, such compositions may be administered by parenteral techniques such as subcutaneous, intravenous and intraperitoneal injections, including delivery in an irrigation fluid used to wash body wound areas, catheterization and the like. Average quantities of the inflammatory cytokine and/or the above recited related agents may vary and in particular should be based upon the recommendations and prescription of a qualified physician or veterinarian.

As stated above and as indicated earlier, antibodies and drugs that modulate the production or activity of the inflammatory cytokine may possess certain therapeutic applications and may thus be utilized for the purpose of treating the effects attributable to the action of the inflammatory cytokine, such as inflammation and fever. In particular, the inflammatory cytokine may be used to produce antibodies to itself in a variety of mammals, by known techniques such as the hybridoma technique utilizing, for example, fused mouse spleen lymphocytes and myeloma cells. The resulting antibodies could then be prepared in a suitable pharmaceutical composition and administered to avert or treat the undesired condition. The exact quantities, intervals of administration and administrative techniques respecting such pharmaceutical compositions may vary in accordance with those known in the medical arts, and upon the specific instruction of a qualified physician or veterinarian.

The present invention also relates to a variety of diagnostic applications, including methods for determining the presence of invasive stimuli by reference to their ability to elicit the activities which are affected by the present inflammatory cytokine. As mentioned earlier, the inflammatory cytokine can be used to produce antibodies to itself by a variety of known techniques, and such antibodies could then be isolated and utilized as in tests for the presence of the inflammatory cytokine in suspect mammals.

Antibody(ies) to the peptides of the inflammatory cytokine can be produced and isolated by standard methods including the well known hybridoma techniques. For convenience, the antibody(ies) to the inflammatory cytokines will be referred to herein as Ab_1 and antibody(ies) raised in another species as Ab_2 .

The presence of inflammatory cytokine activity in mammals can be ascertained by the usual immunological procedures applicable to such determinations. A number of useful procedures are known. Three such procedures which are especially useful utilize either the inflammatory cytokine labeled with a detectable label, antibody Ab_1 labeled with a detectable label, or antibody Ab_2 labeled with a detectable label. The procedures may be summarized by the following equations wherein the asterisk indicates that the particle is labeled, and "Cyt" stands for the inflammatory cytokine:

$$A. \quad \text{Cyt}^* + Ab_1 = \text{Cyt}^*Ab_1$$

$$B. \quad \text{Cyt} + Ab^* = \text{Cyt}Ab_1^*$$

$$C. \quad \text{Cyt} + Ab_1 + Ab_2^* = \text{Cyt}Ab_1Ab_2^*$$

The procedures and their application are all familiar to those skilled in the art and are presented herein as illustrative and not restrictive of procedures that may be utilized within the scope of the present invention. The "competitive"

procedure, Procedure A, is described in U.S. Patent Nos. 3,654,090 and 3,850,752. Procedure C, the "sandwich" procedure, is described in U.S. Patent Nos. RE 31,006 and 4,016,043. Still other procedures are known such as the "double antibody", or "DASP" procedure.

In each instance, the inflammatory cytokine forms complexes with one or more antibody(ies) or binding partners and one member of the complex is labeled with a detectable label. The fact that a complex has formed and, if desired, the amount thereof, can be determined by known methods applicable to the detection of labels.

It will be seen from the above, that a characteristic property of Ab_2 is that it will react with Ab_1 . This is because antibodies raised in one mammalian species have been used in another species as an antigen to raise antibodies such as Ab_2 . For example, Ab_2 may be raised in goats using rabbit antibodies as antigens. Ab_2 therefore would be anti-rabbit antibody raised in goats. For purposes of this description and claims, Ab_1 will be referred to as a primary or anti-inflammatory cytokine antibody, and Ab_2 will be referred to as a secondary or anti- Ab_1 antibody.

The labels most commonly employed for these studies are radioactive elements, enzymes, chemicals which fluoresce when exposed to ultraviolet light, and others.

A number of fluorescent materials are known and can be utilized as labels. These include, for example, fluorescein, rhodamine and auramine. A particular detecting material is anti-rabbit antibody prepared in goats and conjugated with fluorescein through an isothiocyanate.

The peptides of the inflammatory cytokine or their binding partner(s) can also be labeled with a radioactive element or with an enzyme. The radioactive label can be detected by any of the currently available counting procedures. The preferred isotope may be selected from ^{14}C , ^{131}I , 3H , ^{125}I and ^{35}S .

Enzyme labels are likewise useful, and can be detected by any of the presently utilized colorimetric, spectrophotometric, fluorospectrophotometric or gasometric techniques. The enzyme is conjugated to the selected particle by reaction with bridging molecules such as carbodiimides, diisocyanates, glutaraldehyde and the like. Many enzymes which can be used in these procedures are known and can be utilized. The preferred are peroxidase, β -glucuronidase, β -D-glucosidase, β -D-galactosidase, urease, glucose oxidase plus peroxidase and alkaline phosphatase. U.S. Patent Nos. 3,654,090; 3,850,752; and 4,016,043 are referred to by way of example for their disclosure of alternate labeling material and methods.

A particular assay system developed and utilized in accordance with the present invention, is known as a receptor assay. In a receptor assay, the material to be assayed is appropriately labeled and then certain cellular test colonies are inoculated with a quantity of both the labeled and unlabeled material after which binding studies are conducted to determine the extent to which the labeled material binds to the cell receptors. In this way, differences in affinity between materials can be ascertained.

Accordingly, a purified quantity of the inflammatory cytokine may be radiolabeled, after which binding studies would be carried out using for example, recently differentiated neutrophils. Solutions would then be prepared that contain various quantities of labeled and unlabeled inflammatory cytokine and unknown cell samples would then be inoculated and thereafter incubated. The resulting cell monolayers would then be washed, solubilized and then counted in a gamma counter for a length of time sufficient to yield a standard error of <5%. These data are then subjected to Scatchard analysis after which observations and conclusions regarding material activity can be drawn. While the foregoing protocol is exemplary, it illustrates the manner in which a receptor assay may be performed and utilized, in the instance where the cellular binding ability of the assayed material may serve as a distinguishing characteristic.

In a further embodiment of this invention, commercial test kits suitable for use by a medical specialist may be prepared to determine the presence or absence of inflammatory cytokine in a suspected mammal. For example, one class of such kits will contain at least a labeled component selected from the inflammatory cytokine or its binding partner, for instance an antibody specific thereto, and directions, of course, depending upon the method selected, e.g., "competitive", "sandwich", "DASP" and the like. The kits may also contain peripheral reagents such as buffers, stabilizers, etc.

Accordingly, a test kit may be prepared for the demonstration of the reaction of a mammalian host to invasive stimuli, comprising:

- (a) a predetermined amount of at least one labeled immunochemically reactive component obtained by the direct or indirect attachment of the present inflammatory cytokine or a specific binding partner thereto, to a detectable label;
- (b) other reagents; and
- (c) directions for use of said kit.

More specifically, the diagnostic test kit may comprise:

- (a) a known amount of the inflammatory cytokine as described above (or a binding partner) generally bound to a solid phase to form an immunosorbent, or in the alternative, bound to a suitable tag, or plural such end products,

etc. (or their binding partners) one of each;
 (b) if necessary, other reagents; and
 (c) directions for use of said test kit.

In a further variation, the test kit may be prepared and used for the purposes stated above, which operates according to a predetermined protocol (e.g. "competitive", "sandwich", "double antibody", etc.), and comprises:

(a) a labeled component which has been obtained by coupling the inflammatory cytokine to a detectable label;
 (b) one or more additional immunochemical reagents of which at least one reagent is a ligand or an immobilized ligand, which ligand is selected from the group consisting of:

- (i) a ligand capable of binding with the labeled component (a);
- (ii) a ligand capable of binding with a binding partner of the labeled component (a);
- (iii) a ligand capable of binding with at least one of the component(s) to be determined; and
- (iv) a ligand capable of binding with at least one of the binding partners of at least one of the component(s) to be determined; and

(c) directions for the performance of a protocol for the detection and/or determination of one or more components of an immunochemical reaction between the inflammatory cytokine and a specific binding partner thereto.

In accordance with the above, an assay system for screening potential drugs effective to modulate the synthesis, release, or activity of the inflammatory cytokine may be prepared. In a first procedure, the test drug could be administered to a stimulated macrophage sample to determine its effect upon the production of the inflammatory cytokine. In an alternate procedure, the inflammatory cytokine may be introduced into a cellular test system such as neutrophils, and the prospective drug may also be introduced into the cell culture, and the culture thereafter examined to observe any changes in the activity of the inflammatory cytokine, either resulting from the addition of the prospective drug alone, or from the effect of added quantities of the known inflammatory cytokine.

The mature amino acid sequences shown in FIGURES 8A and 8B are only illustrative of the proteins useful in the present invention and similar sequences may result in proteins which have substantially equivalent or altered activity as compared to that set forth in FIGURES 8A and 8B. These modifications may be deliberate, for example, such as modifications obtained through site-directed mutagenesis, or may be accidental, such as those obtained through mutations in hosts which are MIP-1 producers. All of these modifications are included in the present invention, as long as the MIP-1-like activity, as defined above, is retained. Accordingly, the definition of MIP-1 and the term "inflammatory cytokine" as used herein specifically includes protein material with peptide components having an amino acid sequence substantially equivalent to that in FIGURES 8A and 8B, either individually or in combination.

Similarly, the term "stimulus" and its plural are intended to apply to invasive events such infection, as well as conditions caused by wounding, and to idiopathic or spontaneous states that may for example originate from cellular or metabolic derangements or other causes.

As indicated earlier, the following example sets forth the details of the isolation and identification of the present inflammatory cytokine, and the observations noted as to its activity, defining both the distinctions and similarities in activity between the present inflammatory cytokine and those factors identified earlier both by applicants and by others in the field. Naturally, the specific materials and techniques set forth hereinafter are exemplary only and may vary, so that the following is presented as illustrative but not restrictive of the present invention.

EXAMPLE

The following experiments were conducted to identify and further characterize the inflammatory cytokine of the present invention. Initially, the mediator substance was cultured, the inflammatory cytokine was isolated and its structure then determined, after which a battery of tests were conducted in an effort to elucidate its activities, and where possible, to establish or refute identity with other known macrophage-derived factors.

MATERIALS AND METHODS

Materials - Purified, recombinant human cachectin/TNF was obtained from Chiron Corp., Emeryville, CA. Purified, recombinant human IL-1 α was the generous gift of Dr. P. Lomedico (Hoffmann LaRoche, Nutley, NJ). All chemicals were the highest grades available from commercial suppliers.

Animals - C3H/HeN mice were obtained from Charles River (Kingston, NY). Mice of the endotoxin-resistant C3H/HeJ strain were obtained from Jackson Laboratories (Bar Harbor, ME).

Cell Culture - The mouse macrophage cell line RAW 264.7 and the cachectin/TNF sensitive cell line L929 were obtained from American Type Culture Collection (Rockville, MD) and maintained in RPMI 1640 or Dulbecco's modified MEM ((DMEM) GIBCO, Grand Island, NY), respectively. Both media were supplemented with 20mM Hepes and 10% fetal bovine serum (Hyclone, Logan, UT). For the production of stimulated RAW 264.7 supernatants, cells were grown in 150 mm tissue culture dishes (Falcon) in RPMI plus 10% fetal bovine serum until they reached confluency. The cells were washed five times in Hanks' balanced salt solution and the medium was replaced with serum-free RPMI supplemented with 1 µg/ml of lipopolysaccharide (LPS W, *E. coli* 0127:B8, Difco, Detroit, MI). The cells were incubated at 37°C for 16-18 hours and the supernatants filtered through 0.22 µm filters.

Purification of MIP-1 - One to five liters of supernatant mediator substance were concentrated 16-40-fold in a DC2 hollow fiber concentration system with a 10,000 dalton molecular weight cutoff (Amicon Corp., Lexington, MA) and diafiltrated against 6 liters of 20 mM Tris buffer, pH 8.0, using the same device. Octyl glucoside was added to the concentrated, diafiltrated supernatant to a final concentration of 1% (w/v) and the mixture was applied to a Mono Q 10/10 (anion exchange (Pharmacia, Rahway, NJ)) column previously equilibrated with 20 mM Tris buffer, pH 8.0, and connected to a fast protein liquid chromatography (FPLC, Pharmacia) apparatus. A linear gradient of 114 ml (total volume) from 0 to 1 M NaCl in the same buffer (and a flow rate of 2 ml/min.) was used for elution.

Samples of each fraction were subjected to polyacrylamide gel electrophoresis in a denaturing system containing sodium dodecyl sulfate (SDS-PAGE) in 10-15% or 10-18% linear gradient slab gels under reducing conditions. Molecular weight standards (BRL, Inc., Bethesda, MD) were run in parallel. Fractions containing MIP-1 eluted in the same region as cachectin/TNF and were easily recognized as a characteristic doublet of approximately 8,000 molecular weight.

Peak MIP-1-containing fractions (as assessed by SDS-PAGE and silver staining) were pooled, concentrated and fractionated on a high-performance gel-filtration column (Superose 12; Pharmacia) previously equilibrated with 100 mM ammonium acetate. MIP-1 was recovered in the void volume of the column and was greater than 95% pure as judged by SDS-PAGE and silver staining. MIP-1 purified in this manner contained approximately 0.2 ng LPS/µg MIP-1.

Heparin Chromatography - Heparin-conjugated Sepharose (Pharmacia) was used to assay the ability of MIP-1 to bind heparin. A C10/20 column (Pharmacia) packed with 8 ml of gel was attached to an FPLC apparatus and equilibrated with 20mM Tris, pH 8.0. Two ml of 12-fold concentrated and diafiltrated RAW 264.7 supernatant (as above) was applied to the column and a linear gradient of 0 to 2 M NaCl in the same buffer was used for elution.

Chromatofocusing - Eight micrograms of a peak MIP-1-containing fraction from Mono Q chromatography was equilibrated in 25 mM bis-Tris plus 10% betaine (w/v), pH 7.1, and applied to a Mono P column previously equilibrated in the same buffer. Protein was eluted with a linear gradient of Polybuffer 74 (Pharmacia) (1:10 in double-distilled water) with 10% betaine (pH 4.0), resulting in a descending pH gradient ranging from 7 to 4.

Protein Assay - Protein content was measured by an assay (Bradford, M., ANAL. BIOCH. 72:248-254, (1976)) using BSA as a standard (Bio-Rad, Richmond, CA).

Endotoxin Assay - Endotoxin levels were determined using a chromogenic limulus assay (Whittaker M.A. Bioproducts, Walkersville, MD) according to the instructions of the manufacturer.

Protein Sequencing - Purified MIP-1 was sequenced by the Rockefeller University protein sequencing facility. The Dayhoff protein sequence bank was searched for homologous amino acid sequences using the computer program d-FAST-P.

In Vivo Inflammatory Activity - Polymorphonuclear leukocyte (PMN) infiltration was evaluated using footpad injections, according to Granstein, R.D., et al., J. CLIN. INVEST. 77:1020-1027 (1986). Briefly, female C3H/HeJ mice (6-12 weeks) were lightly anesthetized with phenobarbital (25 mg/kg body weight, i.p.). Animals were randomized to receive a subcutaneous footpad injection of 0.05 ml containing 10⁻¹⁰ moles N-formylmethionylleucylphenylalanine (fMLP); 10, 100 or 1000 ng of recombinant human IL-1α or recombinant human cachectin/TNF; or 1, 10, 100, or 1000 ng of murine MIP-1 (purified as above) in RPMI 1640 with 0.1% fetal bovine serum. RPMI 1640 with 0.1% fetal bovine serum alone served as a control. In some cases, mice received the test substance in one hind-limb foot-pad and the control carrier in the contralateral hindlimb. In other cases, a randomized block design was employed. Mice were sacrificed four hours following injection and hindlimbs were fixed in 10% buffered formalin. Hind-limbs were decalcified, embedded in paraffin and thin-sections of footpads were stained with hematoxylin and eosin.

In Vitro PMN Migration Assays - Heparinized venous blood was obtained from healthy volunteers. Leukocytes containing greater than 95% PMN's as judged by cell sorter analysis were isolated by Ficoll-Hypaque density gradient centrifugation and dextran sedimentation (Klempner, M.S., et al., J. CLIN. INVEST. 64:996-1002 (1979)). Residual erythrocytes were removed by lysis with hypotonic saline. Cells were resuspended in Gey's balanced salt solution (GBSS, pH 7.4) and 2% bovine serum albumin (BSA) to a final concentration of 2.5 x 10⁶ cells/ml.

In vitro chemokinesis was assayed using a modification of the technique described by Boyden (Boyden, S.V., J. EXP. MED. 115:453-466 (1962)). Bottom wells of blind well chambers were filled with 25 µl of buffer containing the test compound, i.e. fMLP (10⁻⁸ M), MIP-1 or buffer alone; and the top wells filled with 45 µl of GBSS/BSA containing 1.1 x 10⁴ PMN's. The two wells were separated by a cellulose nitrate membrane with a 3 µm pore size (SM 11302, Sartorius,

Westbury, CT). Chambers were incubated at 37°C in a humidified 5% CO₂-95% room air chamber for 45 minutes. Membranes were removed and stained according to a previously described protocol (Hesse, D.G., et al., J. CLIN. INVEST. 73:1078-1085 (1984)). The number of PMN's migrating into the membrane was counted for every 10 µM up to 130 µM using an automated Optomax imaging system (Optomax, Inc., Hollis, NH). Migration was quantitated in three randomly selected fields for each membrane with each sample tested in triplicate. Chemokinesis was defined as the mean distance migrated into the membrane (expressed as a percent) compared to GBSS alone (0%) and that of the positive fMLP control (100%).

Chemokinetic data are expressed as percents (mean ± standard error of the mean (SEM)) of the control chemokinetic response. A one-way analysis of variance (ANOVA) was used to compare the response to MIP-1 with that to GBSS alone in the bottom well of the chamber.

Induction of Hydrogen Peroxide Release - The ability of MIP-1 to elicit the release of H₂O₂ from adherent human PMN or monocytes was tested by the method recently described in detail (Nathan, C.F. 1987, J. CLIN. INVEST. (in press)). In brief, PMN and mononuclear leukocytes in heparinized or citrated blood were isolated in Neutrophil Isolation Medium (Packard Instrument Co., Downer's Grove, IL), washed and plated separately at 1.5 x 10⁴ PMN or 2 x 10⁵ mononuclear cells per well in flat-bottomed, 6-mm diameter polystyrene tissue culture wells that had previously been coated with fetal bovine serum and extensively washed. The assay mixture contained 2.4 nM scopoletin, 0.5 µg horse-radish peroxidase, 1 mM sodium azide and the indicated test agents in a final volume of 0.13 ml of Krebs-Ringer phosphate buffer with glucose at 37°C. Loss of fluorescence of scopoletin due to oxidation by H₂O₂ was recorded at 15- or 30-minute intervals in a plate-reading fluorometer and converted to nM H₂O₂ by microcomputer (de la Harpe, J., et al., J. IMMUN. METHODS 78:323-336 (1985)).

IL-1 and Cachectin/TNF Bioassays - MIP-1 was assayed for IL-1 activity by its ability to stimulate C3H/HeJ thymocytes to undergo blastogenesis in the presence of suboptimal quantities of phytohemagglutinin, as previously described (Moldawer, L.L., et al., J. IMMUN. 138:4270-4274 (1987)).

Cachectin/TNF activity was assayed by its ability to kill actinomycin D-treated L929 murine fibroblasts (Ostrove, J.M., et al., PROC. SOC. EXP. BIOL. MED. 160:354-358 (1979)). Approximately 50,000 L929 cells were plated in each well of a 96-well plate (Falcon) in DME medium containing 1 µg/ml actinomycin D and increasing quantities of MIP-1. After 14-16 hours, the chromogen (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide (MTT)) was added and the cells incubated for an additional 4 hours. Cell viability was assessed by the ability of the cells to reduce the chromogen during this time period by a modification of a known procedure (Mosmann T., J. IMMUN. METHODS 65:55-63 (1985)). The medium was aspirated and the cells lysed with 0.04N hydrochloric acid in isopropanol. After addition of one volume double-distilled water, the extent of chromogen reduction was measured by reading the plates at O.D. 570/690 using an automated ELISA-plate reader and values were compared to a standard cytotoxicity curve obtained in like manner with recombinant human cachectin/TNF.

Cachectin/TNF was also assayed by the suppression of lipoprotein lipase on 3T3-L1 cells as previously described (Beutler, B., et al., J. EXP. MED. 161:984-995 (1985)). The ability of MIP-1 to induce cachectin/TNF in primary cultures of macrophages was assessed by eliciting macrophages with an i.p. injection of two milliliters of sterile thioglycollate broth (DIFCO) and collecting the cells 4 to 6 days later by peritoneal lavage. The cells were washed and resuspended in serum-free RPMI and plated at 10⁶ cells/well in 24-well tissue culture plates. Test substances (LPS, 0.0001-1 µg/ml; MIP-1, 1 µg/ml) were added and the cells incubated at 37°C for 18 hours. The cell-free supernatants were collected and assayed for cachectin/TNF activity by cytotoxicity on L929 cells as described above.

Purification of MIP-1α and MIP-1β: MIP-1 containing fractions from high performance gel filtration chromatography over Superose 12 were pooled, concentrated using a PM-10 membrane in a stirred cell (Amicon Corp., Danvers, MA), and diafiltrated against 0.01M sodium phosphate buffer, pH 6.4. Two components of MIP-1 were then resolved by SDS-hydroxylapatite chromatography according to a known procedure (Moss, B. and E. N. Rosenblum., J. BIOL. CHEM., 247:5194, (1972)). In brief, a 500 µg aliquot of MIP-1 was equilibrated in 0.01 M sodium phosphate buffer, pH 6.4, containing 1% SDS and 1% mercaptoethanol and placed in a boiling water bath for 2 minutes. The sample was immediately diluted 10-fold with 0.01 M sodium phosphate buffer (pH 6.4) containing 0.1% SDS and 1.0 mM DTT (Buffer A), applied directly to a hydroxylapatite column (Bio Gel HPHT, Bio-Rad, Richmond, CA) pre-equilibrated in Buffer A. A 25 ml linear gradient from 0.01 M to 0.35 M sodium phosphate buffer (pH 6.4) containing 0.1% SDS and 1.0 mM DTT was used for elution.

Protein Sequencing: N-terminal amino acid sequence analysis of MIP-1α and MIP-1β were performed on an Applied Biosystems gas phase sequencer. The Dayhoff protein sequence bank was searched for homologous amino acid sequences using the computer program d-FAST-P.

Hydropathicity Plots: The hydropathicity plots of MIP-1α and MIP-1β were calculated by a modification of a known algorithm (Hopp, T. P. and K. R. Woods., PROC. NATL. ACAD. SCI. U.S.A. 78:3824 (1981)).

Construction of cDNA Library: A cDNA library from LPS-stimulated RAW 264.7 cells was obtained as described previously (G. Davatellis, P. Tekamp-Olson, S. D. Wolpe, K. Hermesen, C. Luedke, C. Gallegos, D. Coit, J. Merryweather, and A. Cerami, J. EXP. MED., 167: 1939-1944 (1988)). In brief, confluent monolayers of RAW 264.7 cells were washed

five times in HBSS and covered with serum-free RPMI 1640 culture medium containing 1.0 µg/ml LPS. After incubation at 37°C for 2 hours, total RNA was extracted into 6M guanidinium thiocyanate (Ullrich, A., J. Shine, J. Chirgwin, R. Pictet, E. Tischer, W. J. Rutter, and H. M. Goodman, *SCIENCE* 196:1313 (1977)). Poly(A)+ RNA was then isolated by two cycles of oligo(dT)-cellulose chromatography according to a modification of a known procedure (Maniatis, T., E. F. Fritsch, and J. Sambrook, "Molecular Cloning: A Laboratory Manual." Cold Spring Harbor Laboratory, Cold Spring Harbor, NY, p. 197 (1982)). Double-stranded cDNA was prepared from the poly(A)+ selected RNA according to a known procedure (Gubler, U., and B. J. Hoffman, *GENE* 25:263 (1983)). Internal Eco R1 sites were methylated, Eco R1 linkers added, and the cDNA inserted into the Eco R1 sites of bacteriophage lambda gt10 (Huynh, T. V., R. A. Young, and R. W. Davis, *DNA Cloning: A Practical Approach*, D. M. Glover, ed., IRL Press, Oxford. 149 (1985)).

Construction of the Probe Pools: Two oligonucleotide probe pools corresponding to the "major" sequence were synthesized according to Warner, B. D., M. E. Warner, G. A. Karns, L. Ku, S. Brown-Shimer, and M. S. Urdea, *DNA* 3:401 (1984) against amino acids #22-30 of a partial amino-terminal sequence. This portion of the polypeptide was selected because of its lower degeneracy in the codon dictionary when compared to the remainder of the sequence. The resulting probe pools are two 512-fold degenerate pools of 26 nucleotides in length.

An oligonucleotide probe pool corresponding to amino acids 2-8 of a partial N-terminal sequence of MIP-1β were synthesized as described by a modification of Warner, B. D., M. E. Warner, G. A. Karns, L. Ku, S. Brown-Shimer, and M. S. Urdea, *DNA* 3:401 (1984). This particular sequence was chosen because it was the region of least apparent homology between MIP-1α and MIP-1β sequences.

Screening of the Library: In regard to MIP-1α, nitrocellulose filter lifts of a low-density plating (5x10³ pfu/plate) of the library were hybridized using the synthetic probe pool that had been 5'-end labeled with ³²P-ATP (New England Nuclear, Boston, MA). Following the hybridization, the lifts were washed using the method of Wood et al. (10). After several rounds of screening, 18 recombinant phage clones were isolated and grown in bulk for DNA isolation.

In regard to MIP-1β, duplicate nitrocellulose filter lifts of the plated library (4x10⁵ plaques) were hybridized overnight at 42°C in 4 x SSC, 2x Denhardt's solution, 40 mM sodium phosphate buffer, pH 7.0, 0.3 mg/ml sonicated salmon sperm DNA, 0.1% SDS and 2.5-5x10⁴ cpm/ml/degeneracy of the ³²P-ATP 5' end-labeled synthetic oligonucleotide probe pool. Following hybridization, the filters were washed; the final washes were done under conditions of moderate stringency: 2 x SSC, 0.1% SDS at 50°C. Plaques which were positive on duplicate filters were subjected to a second round of low density plating and screening. In this way two independent positive phage clones were isolated from which DNA was prepared for further analysis.

DNA Sequence Analysis: The cDNA inserts to be analyzed were subcloned into M13 phage vectors and DNA sequencing was performed by the dideoxy-chain termination method of Sanger et al. (F. Sanger and S. Nicklen, R. Coulson, *PROC. NATL. ACAD. SCI. U.S.A.* 74:5463 (1977)).

Blot Hybridization Analysis - Northern blot hybridization was performed by an adaptation of a known method (Lehrach, H., D. Diamond, J. M. Wozney, and H. Boedtker, *BIOCHEMISTRY* 16:4743 (1977)). Total RNA of LPS-stimulated and nonstimulated RAW 264.7 cells were electrophoresed through 1.2% agarose gels and transferred to nitrocellulose filters.

Primer Extension - The synthetic oligonucleotide primer was end labeled using [γ-³²P]ATP (3,000 Ci/mmol, Amersham Corp., Arlington Heights, IL) and the T4 polynucleotide kinase. The primer extension method was a modification of a known method (Walker, M. D., T. Edlund, A. M. Boulet, and W. J. Rutter, *NATURE LOND.* 306:557 (1983)).

RESULTS

Purification of MIP-1 - When supernatants of stimulated RAW 264.7 cells were fractionated by Mono Q (anion exchange) chromatography, MIP-1 was apparent as a distinctive doublet of about 8,000 daltons on SDS-PAGE after silver staining (FIGURE 1). MIP-1 reproducibly eluted within a fraction or two of cachectin/TNF at approximately 0.37 M NaCl and appeared to be produced in approximately the same quantities as judged by silver-staining.

Chromatofocusing revealed that Mono Q-purified MIP-1 eluted at a slightly more acidic pH than cachectin/TNF. This corresponded to a pI of 4.6 (not shown).

In order to further purify MIP-1, advantage was taken of its tendency to aggregate. Aggregation of MIP-1 was observed to occur during the concentration of the crude material and before diafiltration or fractionation on Mono Q (data not shown). When fractionated by gel filtration in phosphate-buffered saline, MIP-1 formed multimers of various molecular weights ranging from approximately 20,000 daltons to material eluting in the void volume (≥2 x 10⁶ daltons; data not shown). In 100 mM ammonium acetate this tendency was exaggerated and the majority of the protein eluted in high molecular weight fractions (FIGURE 2). Under these conditions, MIP-1 of greater than 95% purity, as judged by SDS-PAGE and silver staining, was obtained.

Partial N-terminal amino acid sequence data of purified MIP-1 (FIGURE 3) showed a single major sequence although sequences of two separate batches showed consistent minor amino acids at several specific positions in the N-terminal region. Computer-based analysis of this sequence data revealed no significant homology with any previously

described protein.

Affinity of MIP-1 for Heparin - During the purification of MIP-1, its affinity for heparin (FIGURE 4) was noted. When 2 ml of 12-fold concentrated RAW 264.7 supernatant were applied to a column and eluted with a linear gradient of 0 to 2 M NaCl, MIP-1 was one of two major proteins detectable by SDS-PAGE and silver staining, eluting at approximately 0.7 M NaCl.

Determination of Biological Activities - At concentrations as high as 20 µg/ml, purified MIP-1 did not stimulate blastogenesis of C3H/HeJ thymocytes. Recombinant human IL-1, on the other hand, was active in this assay at concentrations as low as 10 pg/ml (data not shown). Similarly, purified MIP-1 did not kill L929 cells in the presence of actinomycin D even at concentrations of 1 µg/ml whereas recombinant human cachectin/TNF was able to induce killing at concentrations as low as 15 pg/ml (data not shown). Further, purified MIP-1 did not induce down-regulation of lipoprotein lipase in 3T3-L1 cells (data not shown). At 1 µg/ml, purified MIP-1 did not induce cachectin/TNF production by primary thioglycollate-elicited mouse macrophages in the presence of 10 µg/ml polymyxin B (data not shown).

Although free of the above-mentioned IL-1- and cachectin/TNF-like activities, MIP-1 did induce a localized inflammatory response at four hours when injected subcutaneously into the footpads of C3H/HeJ mice. Maximal inflammation occurred when 100 ng of MIP-1 were administered and was characterized primarily by PMN leucocyte infiltration (FIGURE 5, plate A). The control response to an injection of carrier is shown in plate B. The degree of neutrophil infiltration seen with MIP-1 was not as marked as that seen when 10^{-10} moles of fMLP were administered (FIGURE 5, plate C). However, the degree of neutrophil infiltration was comparable to that observed with 10 ng of recombinant cachectin/TNF. Recombinant human IL-1 elicited no inflammatory responses at four hours when administered at these doses (data not shown).

MIP-1 induced chemokinesis in human neutrophils *in vitro*. Data presented in FIGURE 6 represent the mean percent of the control migratory response of five experiments. Values are presented as the percent increases in neutrophil migration relative to the negative GBSS (0%) and positive fMLP 10^{-8} M controls (100%). At concentrations equal to or greater than 100 ng/ml, MIP-1 elicited a significant increase in neutrophil migration ($p < 0.01$ by ANOVA).

Inclusion of polymyxin B (10 µg/ml) had no effect on MIP-1-induced chemokinesis. Further, LPS at concentrations of 10-1000 ng/ml was not active in this assay (data not shown).

Recombinant cachectin/TNF, but not rIL-1 α , triggers a delayed but significant respiratory burst in human PMN, provided the cells are adherent to a surface coated with serum or extracellular matrix proteins (Nathan, C.F. 1987, J. CLIN. INVEST. (in press)). Similarly, MIP-1 at ≥ 1 µg/ml triggered adherent PMN to release H_2O_2 in four experiments, one of which is illustrated in FIGURE 7. Compared to cachectin/TNF tested in parallel cultures, the response to MIP-1 was more delayed (60 minute lag versus 15 minute lag for cachectin/TNF), and the maximal sustained rate was lower (1.2 nmol/min per 10^6 PMN versus 3.0 for cachectin/TNF and 2.1 for PMA). However, the duration of the response was greater (2.5 hours compared to 1 hour for cachectin/TNF) and thus, the total amounts of H_2O_2 released were similar. Because MIP-1 binds heparin, experiments were also performed with PMN isolated from citrated rather than heparinized blood and gave similar results. Neither MIP-1 (not shown) nor cachectin/TNF (Nathan, C.F. 1987, J. CLIN. INVEST. (in press)) triggered H_2O_2 release from monocytes.

DISCUSSION

The data presented above indicate that, while the inflammatory cytokine MIP-1 bears no significant sequence homology to any previously described protein, it shares some of the overlapping properties typical of inflammatory mediators such as cachectin/TNF and IL-1.

MIP-1 was isolated on the basis of its interesting physical properties. As indicated earlier, although MIP-1 migrates as a doublet of about 8,000 daltons on SDS-PAGE, it readily forms high molecular weight aggregates in excess of 2×10^6 daltons as judged by gel filtration. Partial amino acid sequence data show one "major" sequence with "minor" substitutions at several positions.

The binding of MIP-1 to heparin under conditions where the protein is anionic suggests a specific interaction. This is further emphasized by the observation that MIP-1 is one of two major macrophage-secreted proteins that bind to heparin at high salt concentrations. It is possible that MIP-1 may play a role in the coordination of the inflammatory activities of macrophages, mast cells and neutrophils. MIP-1 may also interact with basement membrane proteoglycans during inflammation.

The findings presented here are consistent with the suggestion that either cachectin/TNF or MIP-1 are capable of inducing an inflammatory response. Cachectin/TNF has previously been shown to induce neutrophil chemokinesis (Figari, I.S., et al. 1987, BLOOD (in press); and Ming, W.J., et al., J. IMMUN. 138:1469-1474 (1987)) as well as activation (Shalaby, M.R., J. IMMUN. 135:2069-2073 (1985); and Tsujimoto, M., et al., BIOCH. BIOPHYS. RES. COMMUN. 137: 1094-1100 (1986)). In the present study MIP-1 was shown also to be capable of inducing neutrophil chemokinesis. In addition, at the doses used here, cachectin/TNF and MIP-1 each elicited similar degrees of inflammation *in vivo*. Although others have shown that recombinant IL-1 can induce an inflammatory reaction *in vivo* (Granstein, R.D., et al.,

J. CLIN. INVEST. 77:1020-1027 (1986)), no such effect was found here; it is possible that the recombinant human IL-1 α used here is less active in this regard than the murine IL-1 α used in published experiments (Granstein, R.D., et al., J. CLIN. INVEST. 77:1020-1027 (1986)).

It is unlikely that the effects of MIP-1 administration are due to cachectin/TNF contamination as there was no cachectin/TNF bioactivity detected by L929 cytotoxicity assay at the doses used. Further, MIP-1 did not induce primary thioglycollate-elicited macrophages to produce cachectin/TNF. Endotoxin contamination was ruled out as an explanation for the chemokinetic effect, as chemokinesis was not affected by the presence of polymyxin B; and LPS itself, at concentrations greater than were present in the MIP-1 assays, had no chemokinetic effect.

The inflammation induced by MIP-1 was observed in mice of the endotoxin-resistant C3H/HeJ strain using preparations with low levels of endotoxin contamination (0.2 ng LPS/ μ g MIP-1).

As described previously, native murine MIP-1 is isolated as a doublet with nearly identical subunit molecular weights of approximately 8000 daltons. Although two MIP-1 components are separated to some extent by SDS-PAGE, their electrophoretic mobilities are so similar that preparative SDS-PAGE appeared an impractical means of purification. Native MIP-1 (doublet) was subjected to SDS-hydroxylapatite chromatography, a technique which has been used successfully to separate protein subunits of similar electrophoretic mobility (B. Moss and E. N. Rosenblum, J. BIOL. CHEM. 247:5194 (1972)). As can be seen in FIGURE 13, two distinct protein peaks are observed following fractionation of native MIP-1 on a hydroxylapatite column in the presence of SDS. The first peak elutes at 0.24 M sodium phosphate and the second peak elutes at 0.27 M sodium phosphate. N-terminal amino acid and SDS-PAGE analyses of the column fractions revealed that the first peak corresponded to the lower molecular weight band of MIP-1 now referred to as MIP-1 α , while the second peak corresponded to the higher molecular weight band referred to as MIP-1 β . Using this technique, each component was obtained in pure form (>95% as judged by SDS-PAGE) for N-terminal amino acid sequence analysis.

To elucidate the molecular structure of murine MIP-1 α , a cDNA clone was isolated containing the sequence coding for MIP-1 α . As a first step, the mouse macrophage cell line RAW 264.7 was stimulated with LPS. Since RAW 264.7 cells have been shown to be a source of MIP-1 α protein after LPS stimulation, the MIP-1 α mRNA was expected to be highly reiterated in these LPS-induced cells.

Poly(A)⁺RNA was prepared from total RNA by two cycles of lambda oligo-dT-chromatography and a cDNA library was constructed in lambda gt10. The cloning efficiency was 10⁶ clones/ μ g of poly(A)⁺RNA. The library was amplified and shown to contain inserts of greater than 1,000 bp in above 60% of recombination plaques. Nitrocellulose filter lifts of a low-density plating of the library were screened using two synthetic oligonucleotide pools that were based on the consensus partial NH₂-terminal amino acid sequence of purified MIP-1 (S. D. Wolpe, G. Davatelis, B. Sherry, B. Beutler, D.G. Hesse, H.T. Nguyen, L. L. Moldawer, C. F. Nathan, S. F. Lowrey, and A. Cerami, J. EXP. MED. 167:570 (1987)). Each pool consisted of a 512-fold degeneracy pool 26 nucleotides in length (FIGURE 9).

After the initial library screening, positive plaques were streaked onto fresh bacterial lawns and a secondary screening was performed by differential plaque hybridization. Replicate lifts of the secondary streaks were hybridized to either ³²P-labeled pool #1 or pool #2. Since the melting temperature (T) of DNA/DNA hybrids can be approximated by the empirical formula: $T = 16.6(\log[\text{Na}^+] + 0.41(\%[\text{G}+\text{C}])) + 81.5 - 500/\text{number of bp in homology}$, one of the probe pools was effectively eliminated through the differential melting temperatures of the hybrids based on a 26-bp homology. By using a tetramethylammonium chloride washing technique (W. Wood, I. J. Gitschier, L. A. Laskey, and R. M. Lawn, PROC. NATL. ACAD. SCI. USA. 82:1585 (1985)), which abolishes the preferential melting of A-T vs. G-C base pairs, the melting temperature (T_m) becomes dependent simply on the length of the hybrid.

After several rounds of differential hybridization, probe pool #1 yielded 18 recombinant phage clones out of 10⁴ screened that hybridized under maximally stringent conditions for MIP-1 α . All of the plaques were purified and DNA was prepared from each. The recombinant phage clone 52 appeared to contain the largest cDNA Eco-RI insert of about 750 bp and was chosen for further characterization. The complete nucleotide sequence of cDNA clone 52, as well as 262 bp of 5' sequence of another, partially overlapping clone, 32, have been determined and are shown in FIGURE 10. The latter clone, which was isolated in a later screening, had a smaller Eco RI insert than clone 52, but a larger 5'-end fragment and therefore presumably less poly(A) tail. The MIP-1 α nucleotide sequence of 763 bp predicts a single open reading frame starting at nucleotide 2. The mature protein sequence, starting at position one, is 69 amino acids in length and comprises the "major" sequence previously defined by NH₂-terminal analysis of the purified MIP-1 protein (S. D. Wolpe, G. Davatelis, B. Sherry, B. Beutler, D.G. Hesse, H.T. Nguyen, L. L. Moldawer, C. F. Nathan, S. F. Lowrey, and A. Cerami, J. EXP. MED. 167:570 (1987)).

The first methionine present in the sequence is found at position -23. This is postulated to be the initiating methionine for the MIP-1 α precursor based on the following observations. Structural analysis of the putative presequence (-23 to -1) indicates that it has features characteristic of typical signal sequences (i.e., α -helix and a hydrophobic core (D. Perlman and H. O. Halvorson, J. MOLE. BIOL., 167:391 (1983)). The predicted initiating ATG has a purine at relative position -3, which has been shown (M. Kozak, CELL. 44:283 (1986)) to have a dominant effect on translation initiation efficiency. Furthermore, in a survey of the frequency of A,C,T,G around the translation start site of 699 vertebrate

mRNAs, 97% had a purine at position -3, 61% having an A at that position (M. Kozak, NUCLEIC ACIDS RES. 15:8125 (1987)).

A primer extension analysis was also performed to determine the amount of 5' sequence lacking from the cDNA clone. A labeled oligonucleotide primer (FIGURE 10) was hybridized to LPS-stimulated RAW 264.7 poly(A)⁺ RNA and elongated with reverse transcriptase. After hybridization, an extended primer of 98 ± 2 nucleotides was obtained (data not shown). After subtracting out the primer length of 25 nucleotides and the sequence 5' to the primer we had previously determined (61 nucleotides), one can conclude that the known sequence is 10-14 nucleotides short of a full-length cDNA. While it is possible than an in-frame AUG is present in this cloned region, it seems highly unlikely given that only 14 of 346 sequenced vertebrate mRNAs have 5' noncoding sequences less than 19 nucleotides in length ((M. Kozak, NUCLEIC ACIDS RES. 15:8125 (1987)). It can then be estimated that the 5' untranslated sequence is about 82 nucleotides, well within the 20-100 nucleotide length of most vertebrate 5' noncoding regions sequenced to date.

The proposed pre-MIP-1 α is 92 amino acids in length. There are no consensus Asn-X-Ser, Thr sites for N-linked glycosylation evident in the molecule. There are 7 cysteines, 3 in the presequence and 4 in the mature sequence. The codon usage of the putative pre-MIP-1 α agrees well with that determined for 66 other sequenced murine genes (T. Maruyama, T. Gojobori, S. Aota, and T. Ikemura, NUCLEIC ACIDS RES. 14(Suppl):r151 (1986)). Initially, the peptide bore no significant sequence similarity to any protein as defined at that time by the d-fast-P program homology search (D.J. Lipman and W. R. Pearson, SCIENCE, 227:1435, (1985)) of the Dayhoff protein data base. Similarly, the DNA sequence was also compared against GenBank genetic sequence data with a negative result.

In the 3'-untranslated region, there is a single consensus polyadenylation site at bp 711 to 716. There are also 4 sequences that have only one mismatch to a known cytokine consensus 3'-untranslated sequence (Copenning Application Serial No. 017,360, filed February 24, 1987, the disclosure of which is incorporated herein by reference. See also, D. Caput, B. Beutler, K. Hartog, R. Thayer, S. Brown-Shimer, and A. Cerami, PROC. NATL. ACAD. SCI. 83:1670 (1986)). The 3'-untranslated consensus cytokine sequence (TATT)_n is also present (R. Reeves, A.G. Spies, M.S. Nissen, L.D. Buch, A.D. Weinberg, P.J. Barr, N.S. Maguuson and J.A. Maguuson, PROC. NATL. ACAD. SCI. USA 83:3228 (1986). When n=2 and one mismatch is allowed, four of these sequences are found. There is an overlap in three of these between the sequence defined by Caput et al. and that defined by Reeves et al.

Since MIP-1 is an inducible protein, the expression of murine MIP-1 α mRNA by Northern blot hybridization in RAW 264.7 cellular DNA was also studied. As shown in FIGURE 11, total RNA from LPS-induced cells exhibited a positive hybridization band with an estimated size of 800 bp, while total RNA from uninduced cells showed very little of a positive signal at that or any other size. In a time-course study of the induction of murine MIP-1 α mRNA by endotoxin in these same cells (FIGURE 12), murine MIP-1 mRNA is detected within 1 hour after LPS stimulation and peaks between 8-16 hours after LPS stimulation. This time course differs from the appearance of either murine TNF- α /cachectin or IL-1 α mRNAs when their respective plasmid probes were hybridized to the same blot.

An mRNA produced by human tonsillar lymphocytes in response to mitogen was reported by Obaru, M. Fukuda, S. Maeda, and K. Shimada, J. BIOCHEM. 99:885 (1986). While the sequence is not listed in the Dayhoff protein data base or the GenBank genetic sequence data base, there is a 75.3% amino acid sequence similarity between that protein and murine MIP-1 α . The relationship between these proteins is not known.

Results of N-terminal sequence analysis of the higher molecular weight component of MIP-1 (now referred to as MIP-1 β) is shown in FIGURE 14B. The "minor" residues observed at positions 3 and 7 in the original consensus N-terminal amino acid sequence correspond to amino acid differences between MIP-1 β and MIP-1 α . In FIGURE 14C the original N-terminal amino acid consensus sequence for native MIP-1 is given for comparison.

A cDNA clone containing the coding sequence for MIP-1 β was isolated and characterized. To accomplish this, a cDNA library from LPS-stimulated RAW 264.7 cells was prepared. The oligonucleotide probe pool used to screen the cDNA library was generated against the sequence underlined in FIGURE 14B. Three of these seven MIP-1 β amino acids differ from the corresponding sequence of MIP-1 α . The probe pool utilized for screening the library was

5' -CCXATGGGX^{*}T^{*}CGA^{*}CCXCC-3'.

The third position choices (*) were made based on the codon usage reported for cloned murine genes (F. Sanger, S. Nicklen, and R. Coulson, PROC. NATL. ACAD. SCI. (U.S.A.) 74:5463, (1977) and the codon usage of MIP-1 α .

Utilizing the labeled probe pool, the library was screened under conditions of moderate stringency. Two independent clones were isolated out of 4×10^5 recombinant phage plaques screened. This was a considerably lower frequency than expected. Upon DNA sequencing of the isolated clones, it was found that the choice of C for the third position of the Ser5 codon was incorrect. The correct choice was actually a T thereby resulting in no perfect match of any of the probe pool sequences to the actual MIP-1 β sequence. Thus, MIP-1 β sequence representation in the library is likely to be underestimated based on hybridization with the above probe pool. Subsequent screening of the library with unique oligonucleotide probes specific for comparable regions of MIP-1 α and MIP-1 β indicate that MIP-1 β -specific sequences

are 5-fold less abundant than MIP-1 α sequences.

Following plaque purification, insert DNA (≈ 700 bp) from the two positive recombinant phage was shown to cross-hybridize to the MIP-1 α cDNA probe. Insert cDNA was isolated from each recombinant phage population and cloned into m13 from which the complete nucleotide sequence was determined. The two nucleotide sequences differed only in the length of 5' untranslated sequence present. The longer nucleotide sequence is presented in FIGURE 15.

The MIP-1 β cDNA is 650 base pairs (which by primer extension analysis is no more than 11-12 nucleotides short of a complete cDNA sequence). The nucleotide sequence of MIP-1 β contains a single open reading frame beginning with the first ATG codon encountered at the 5' end of the sequence (nucleotides +62 to +64) after an in-frame stop codon. The methionine specified by this codon defines the start of a putative signal sequence (residues -23 and -1) with characteristic features including an α -helix and a centrally located hydrophobic region (D. Perlman, and H. O. Halvorson, J. MOL. BIOL., 167:391 (1983)). The sequence surrounding this ATG codon conforms to the consensus sequence shared by many mRNAs of higher eukaryotes (M. Kozak, NATURE, LONDON, 308:241 (1984)).

The TGA termination triplet is located 91 codons downstream of the initiating codon. The 3' untranslated region of MIP-1 β is comprised of 315 nucleotides and contains the hexanucleotide AATAAA (nucleotides +283 to +288) which precedes the site of polyadenylation in many eukaryotic mRNAs (N.J. Proudfoot and G. G. Brownlee, NATURE, LONDON 263:211 (1976)).

There is a single sequence at nucleotides +174 to +181 which precisely matches a known cytokine 3' untranslated consensus sequence (TTATTTAT) that is characteristic of many immunomodulatory proteins. In addition, there are two additional sequences present that have a single mismatch to this consensus sequence (nucleotides +165 to +175 and nucleotides +185 to +192).

The mature protein sequence, starting at position 1, is 69 amino acids in length. The molecular weight of the mature protein as determined from its cDNA clone is 7832 daltons which agrees with the molecular weight predicted by SDS-PAGE. The amino acid sequence predicted from the cloned DNA sequence is consistent with the first 13 amino acids obtained from N-terminal amino acid sequencing of purified native MIP-1 β .

MIP-1 β has a single N-linked glycosylation site present in the mature protein at amino acids 53 to 55 (Asn-Pro-Ser). Whether native MIP-1 is actually glycosylated at this position has not yet been determined, but it is well recognized that proline at position X in the consensus Asn-X-Ser, Thr signal for N-linked glycosylation results in impaired or no glycosylation at that site (I. Moronen, and E. Karjalainen, BIOCHEM. BIOPHYS. ACTA., 788:364 (1984)).

Hydropathicity plots for MIP-1 α and MIP-1 β which estimate the predicted polarity profiles of the two proteins are shown in FIGURE 16. It is clear from FIGURE 16 that the local polarity distributions within MIP-1 α and MIP-1 β are strikingly similar.

The entire nucleotide sequence of the murine MIP-1 β cDNA was compared to sequences in the Genbank nucleotide database (rodent, primate, other mammals and other vertebrate libraries) as well as to the MIP-1 α cDNA sequence (G. Davatelis, P. Tekamp-Olson, S. D. Wolpe, K. Hermesen, C. Luedke, C. Gallegos, D. Coit, J. Merryweather, and A. Cerami, J. EXP. MED., 167: 1939-1944 (1988)). MIP-1 β and MIP-1 α cDNAs are 56.7% identical. The only significant homology found in Genbank was the human LD78 cDNA clone isolated from a T cell lymphocyte cDNA library on the basis that its mRNA was induced by either the tumor promoter PMA or by phytohemagglutinin (K. Obaru, M. Fukada, S. Maeda, and K. Shimada, J. BIOCHEM., 99:885 (1986)). Murine MIP-1 β cDNA showed 57.1% identity in a 592 nucleotide overlap to human LD78 cDNA, murine MIP-1 α cDNA showed even higher homology, 69% identity in a 746 nucleotide overlap.

When the predicted amino acid sequence of MIP-1 β was tested for homology to sequences in the Dayhoff database using the p-Fast-D computer homology algorithm, no strikingly high homology was found. However, comparison of the predicted protein sequences of murine MIP-1 β , murine MIP-1 α , human LD78 as well as the recently reported predicted sequences for a murine cytokine (JE) inducible by PDGF, IL-1, or double-stranded RNA (P. R. Burd, G. J. Freeman, S. D. Wilson, M. Berman, R. DeKruyff, P. R. Billings, and M. E. Dorf, J. IMMUNOL., 139:3126 (1987) and a murine T-cell activation protein (TCA3) (B. F. Rollins, E. D. Morrison, and C. D. Stiles, PROC. NATL. ACAD. SCI. U.S.A., 85:3738 (1988)) indicates that these proteins are noticeably homologous. The deduced amino acid sequence of MIP-1 β shows 59.8% identity to that of MIP-1 α and 58.7%, 38.9% and 31.9% identity to the predicted amino acid sequences of LD78, JE and TCA3 respectively. Common to all these sequences is the presence of four conserved cysteines in each of the mature peptide sequences. Interestingly, the predicted amino acid sequence of murine MIP-1 α is more homologous to that of human LD78 (75.3% identity) than it is to the predicted amino acid sequence of murine MIP-1 β (59.8% identity). Thus, these proteins share similarities in sequence that appear to define a family of peptides which may be involved in inflammatory and/or immune responses.

Claims

1. An inflammatory cytokine comprising a protein in purified form capable of binding to heparin, inducing localized

inflammation characterized by polymorphonuclear cell infiltration when administered subcutaneously and inducing in vitro polymorphonuclear cell chemokinesis, while lacking the ability to suppress the activity of the anabolic enzyme lipoprotein lipase, cause the cytotoxicity of cachectin/TNF-sensitive cells, stimulate the blastogenesis of endotoxin-resistant C3H/HeJ thymocytes, or induce the production of cachectin/TNF by primary thioglycollate-elicited mouse macrophage cells, which protein is anionic under physiological conditions and has an apparent molecular weight of approximately 8000 daltons as determined by SDS-PAGE.

2. The inflammatory cytokine of Claim 1 wherein said cytokine binds to heparin at high salt concentrations, and tends to form aggregates of high molecular weight greater than about 10^6 daltons in low salt buffers.
3. The inflammatory cytokine of Claim 1 wherein said cytokine is capable of inducing fever in rabbits and inducing superoxide formation or respiratory burst in human neutrophils in vitro.
4. The inflammatory cytokine of Claim 1 wherein said cytokine is derivable from animal cells that may have been incubated with a stimulator material such as might accompany an invasive stimulus.
5. The inflammatory cytokine of Claim 1 wherein said cytokine is derived from cells which are produced by clonal replication.
6. The inflammatory cytokine of Claim 1 having the amino acid sequence substantially equivalent to that set forth in FIGURE 10.
7. The inflammatory cytokine of Claim 1 having the amino acid sequence substantially equivalent to that set forth in FIGURE 8B.
8. The inflammatory cytokine of Claim 1 wherein said cytokine comprises a peptide doublet having the amino acid sequences substantially equivalent to those set forth in Figures 8A and 8B.
9. The inflammatory cytokine of Claim 1 labeled with a detectable label.
10. The inflammatory cytokine of Claim 9 wherein the label is an enzyme.
11. The inflammatory cytokine of Claim 10 wherein the label is selected from the group consisting of peroxidase, β -glucuronidase, β -D-glucosidase, β -D-galactosidase, urease, glucose oxidase plus peroxidase, galactose oxidase plus peroxidase and alkaline phosphatase.
12. The inflammatory cytokine of Claim 9 wherein the label is a chemical which fluoresces when exposed to ultraviolet light.
13. The inflammatory cytokine of Claim 12 wherein the chemical is selected from the group consisting of fluorescein, rhodamine, and auramine.
14. The inflammatory cytokine of Claim 9 wherein the label is a radioactive element.
15. The inflammatory cytokine of Claim 14 wherein the radioactive element is selected from the group consisting of ^{14}C , ^{125}I , ^{131}I , ^{35}S and ^3H .
16. A method for measuring the presence of an inflammatory cytokine comprising a protein in purified form capable of binding to heparin, inducing localized inflammation characterized by polymorphonuclear cell infiltration when administered subcutaneously and inducing in vitro polymorphonuclear cell chemokinesis, while lacking the ability to suppress the activity of the anabolic enzyme lipoprotein lipase, cause the cytotoxicity of cachectin/TNF-sensitive cells, stimulate the blastogenesis of endotoxin-resistant C3H/HeJ thymocytes, or induce the production of cachectin/TNF by primary thioglycollate-elicited mouse macrophage cells, said cytokine being anionic under physiological conditions and having an apparent molecular weight of approximately 8000 daltons as determined by SDS-PAGE, wherein said inflammatory cytokine is measured by:
 - A. preparing at least one sample of said inflammatory cytokine from animal cells that have been exposed to a corresponding number of distinct known invasive stimuli;

- B. preparing at least one corresponding antibody or binding partner directed to said inflammatory cytokine samples;
 - C. placing a detectible label on a material selected from the group consisting of said inflammatory cytokine samples and said antibody or binding partners thereto;
 - 5 D. immobilizing a material selected from the group consisting of the material from Step C that is not labeled, and a biological sample from a mammal in which said inflammatory cytokine is suspected, on a suitable substrate;
 - E. placing the labeled material from Step C in contact with said biological sample, and in contact with the immobilized material;
 - 10 F. separating the material from Step C that is bound to said immobilized material from material from Step C not bound to said immobilized material; and
 - G. examining said bound material for the presence of said labeled material.
17. A method for measuring the binding sites for an inflammatory cytokine comprising a protein in purified form which is anionic under physiological conditions and has an apparent molecular weight of approximately 8000 daltons as determined by SDS-PAGE and which is capable of binding to heparin, inducing localized inflammation characterized by polymorphonuclear cell infiltration when administered subcutaneously and inducing in vitro polymorphonuclear cell chemokinesis, while lacking the ability to suppress the activity of the anabolic enzyme lipoprotein lipase, cause the cytotoxicity of cachectin/TNF-sensitive cells, stimulate the blastogenesis of endotoxin-resistant C3H/HeJ thymocytes, or induce the production of cachectin/TNF by primary thioglycollate-elicited mouse macrophage cells, wherein the binding sites for said inflammatory cytokine are measured by:
- 15 A. preparing at least one sample of said inflammatory cytokine from a corresponding number of distinct known invasive stimuli;
 - 25 B. placing a detectible label on said inflammatory cytokine sample;
 - C. placing the labeled inflammatory cytokine sample in contact with a biological sample from a mammal in which binding sites for said cytokine are suspected; and
 - D. examining said biological sample in binding studies for the presence of said labeled inflammatory cytokine sample.
 - 30
18. The method of Claim 16 comprising a method for measuring the presence of an inflammatory cytokine associated with a given invasive stimulus in mammals.
19. The method of Claim 16 comprising a method for determining the presence of invasive or idiopathic stimuli in mammals.
- 35 20. The method of Claim 16 wherein said invasive stimulus is an infection.
21. The method of Claim 16 wherein said invasive stimulus is selected from the group consisting of bacterial infection, viral infection, protozoal infection, tumorous mammalian cells, and toxins.
- 40 22. The method of Claim 16 wherein said inflammatory cytokine is prepared by:
- A. isolating a colony of mammalian cells;
 - 45 B. incubating said cells with said stimulator material for a period of time sufficient for said stimulator material to induce said cells to produce said inflammatory cytokine; and
 - C. isolating said inflammatory cytokine from said cells.
23. The method of Claim 22 wherein said stimulator material comprises an endotoxin.
- 50 24. The method of Claim 23 wherein said endotoxin comprises lipopolysaccharide.
25. A method of testing the ability of a drug to modulate the production and/or activity of a inflammatory cytokine comprising a protein in purified form capable of reacting with a receptor for the inflammatory cytokine on cells in the mammalian body which comprises culturing a colony of test cells which has said receptor in a growth medium containing the inflammatory cytokine, adding the drug under test and thereafter measuring the reactivity of said drug with the said receptor on said colony of test cells, said inflammatory cytokine comprising a protein material capable of binding to heparin, inducing localized inflammation characterized by polymorphonuclear cell infiltration
- 55

- when administered subcutaneously and inducing in vitro polymorphonuclear cell chemokinesis, while lacking the ability to suppress the activity of the anabolic enzyme lipoprotein lipase, cause the cytotoxicity of cachectin/TNF-sensitive cells, stimulate the blastogenesis of endotoxin-resistant C3H/HeJ thymocytes, or induce the production of cachectin/TNF by primary thioglycollate-elicited mouse macrophage cells, said protein material being anionic under physiological conditions and having an apparent molecular weight of approximately 8000 daltons as determined by SDS-PAGE.
26. The method of Claim 25 wherein said inflammatory cytokine is anionic under physiological conditions and binds to heparin at high salt concentrations, and tends to form aggregates of high molecular weight greater than about 10^6 daltons in low salt buffers.
27. The method of Claim 25 wherein said inflammatory cytokine is capable of inducing fever in rabbits and inducing superoxide formation or respiratory burst in human neutrophils in vitro.
28. The method of Claim 25 wherein said inflammatory cytokine is derivable from animal cells that may have been incubated with a stimulator material such as might accompany an invasive stimulus.
29. The method of Claim 25 wherein said inflammatory cytokine is derived from cells which are produced by clonal replication.
30. An assay system for screening drugs and other agents for ability to modulate production and/or activity of an inflammatory cytokine comprising an observable cellular test colony inoculated with an inflammatory cytokine comprising a protein in purified form capable of binding to heparin, inducing localized inflammation characterized by polymorphonuclear cell infiltration when administered subcutaneously and inducing in vitro polymorphonuclear cell chemokinesis, while lacking the ability to suppress the activity of the anabolic enzyme lipoprotein lipase, cause the cytotoxicity of cachectin/TNF-sensitive cells, stimulate the blastogenesis of endotoxin-resistant C3H/HeJ thymocytes, or induce the production of cachectin/TNF by primary thioglycollate-elicited mouse macrophage cells, said protein being anionic under physiological conditions and having an apparent molecular weight of approximately 8000 daltons as determined by SDS-PAGE.
31. The assay system of Claim 30 wherein said cytokine is anionic under physiological conditions and binds to heparin at high salt concentrations, and tends to form aggregates of high molecular weight greater than about 10^6 daltons in low salt buffers.
32. The assay system of Claim 30 wherein said cytokine is capable of inducing fever in rabbits and inducing superoxide formation or respiratory burst in human neutrophils in vitro.
33. The assay system of Claim 30 wherein said inflammatory cytokine is derivable from animal cells that may have been incubated with a stimulator material such as might accompany an invasive stimulus.
34. The assay system of Claim 30 wherein said inflammatory cytokine is derived from cells which are produced by clonal replication.
35. A test kit for the demonstration of an inflammatory cytokine in serum or an aqueous medium, comprising:
- A. a predetermined amount of at least one labeled immunochemically reactive component obtained by the direct or indirect attachment of an inflammatory cytokine or a specific binding partner thereto, to a detectable label, said inflammatory cytokine comprising a protein which is anionic under physiological conditions and has an apparent molecular weight of approximately 8000 daltons as determined by SDS-PAGE and which is capable of binding to heparin, inducing localized inflammation characterized by polymorphonuclear cell infiltration when administered subcutaneously and inducing in vitro polymorphonuclear cell chemokinesis, while lacking the ability to suppress the activity of the anabolic enzyme lipoprotein lipase, cause the cytotoxicity of cachectin/TNF-sensitive cells, stimulate the blastogenesis of endotoxin-resistant C3H/HeJ thymocytes, or induce the production of cachectin/TNF by primary thioglycollate-elicited mouse macrophage cells,
 - B. other reagents; and
 - C. directions for use of said kit.
36. The test kit of Claim 35 wherein said inflammatory cytokine is anionic under physiological conditions and binds to

heparin at high salt concentrations, and tends to form aggregates of high molecular weight greater than about 10^6 daltons in low salt buffers.

37. The test kit of Claim 35 wherein said inflammatory cytokine is capable of inducing fever in rabbits and inducing superoxide formation or respiratory burst in human neutrophils in vitro.
38. The test kit of Claim 35 wherein said inflammatory cytokine is derivable from animal cells that may have been incubated with a stimulator material such as might accompany an invasive stimulus.
39. The test kit of Claim 35 wherein said inflammatory cytokine is derivable from cells which are produced by clonal replication.
40. The test kit of Claim 35 wherein the label is an enzyme.
41. Use, for the preparation of a pharmaceutical composition for the treatment of inflammation and/or fever in mammals, of a material selected from the group consisting of an antibody to an inflammatory cytokine comprising a protein in purified form, an agent capable of inhibiting the production of said inflammatory cytokine comprising a protein in purified form, an agent not an antibody to said inflammatory cytokine comprising a protein in purified form capable of acting as an antagonist to said inflammatory cytokine, said inflammatory cytokine comprising a protein in a purified form that is anionic under physiological conditions and has an apparent molecular weight of approximately 8000 daltons as determined by SDS-PAGE and that is capable of binding to heparin, inducing localized inflammation characterized by polymorphonuclear cell infiltration when administered subcutaneously and inducing in vitro polymorphonuclear cell chemokinesis, while lacking the ability to suppress the activity of the anabolic enzyme lipoprotein lipase, cause the cytotoxicity of cachectin/TNF-sensitive cells, stimulate the blastogenesis of endotoxin-resistant C3H/HeJ thymocytes, or induce the production of cachectin/TNF by primary thioglycollate-elicited mouse macrophage cells.
42. Use of the material as claimed in Claim 41 for the preparation of a pharmaceutical composition for treatment of inflammation and/or fever in mammals, characterized in that said inflammatory cytokine binds to heparin at high salt concentrations, and tends to form aggregates of high molecular weight greater than about 10^6 daltons in low salt buffers.
43. Use of the material as claimed in Claim 41 for the preparation of a pharmaceutical composition for treatment of inflammation and/or fever in mammals, wherein said cytokine is capable of inducing fever in rabbits and inducing superoxide formation or respiratory burst in human neutrophils in vitro.
44. Use of the material as claimed in Claim 41 for the preparation of a pharmaceutical composition for treatment of inflammation and/or fever in mammals, wherein said inflammatory cytokine is derivable from animal cells that may have been incubated with a stimulator material such as might accompany an invasive stimulus.
45. Use of the material as claimed in Claim 41 for the preparation of a pharmaceutical composition for treatment of inflammation and/or fever in mammals, wherein said inflammatory cytokine is derived from cells which are produced by clonal replication.
46. Use, for the preparation of a pharmaceutical composition for preventing the occurrence of inflammation and/or fever in mammals, of a material selected from the group consisting of an antibody to an inflammatory cytokine comprising a protein in purified form, an agent capable of inhibiting the production of said inflammatory cytokine comprising a protein in purified form, an agent not an antibody to said inflammatory cytokine comprising a protein in purified form capable of antagonizing the activity of said inflammatory cytokine, and mixtures thereof, in an amount effective to avert the onset of said inflammation and/or said fever, said inflammatory cytokine comprising a protein in purified form that is anionic under physiological conditions and has an apparent molecular weight of approximately 8000 daltons as determined by SDS-PAGE and that is capable of binding to heparin, inducing localized inflammation characterized by polymorphonuclear cell infiltration when administered subcutaneously and inducing in vitro polymorphonuclear cell chemokinesis, while lacking the ability to suppress the activity of the anabolic enzyme lipoprotein lipase, cause the cytotoxicity of cachectin/TNF-sensitive cells, stimulate the blastogenesis of endotoxin-resistant C3H/HeJ thymocytes, or induce the production of cachectin/TNF by primary thioglycollate-elicited mouse macrophage cells.

47. Use of the material as claimed in Claim 46 for the preparation of a pharmaceutical composition for preventing the occurrence of inflammation and/or fever in mammals, wherein said inflammatory cytokine is anionic under physiological conditions and binds to heparin at high salt concentrations, and tends to form aggregates of high molecular weight greater than about 10⁶ daltons in low salt buffers.
48. Use of the material as claimed in Claim 46 for the preparation of a pharmaceutical composition for preventing the occurrence of inflammation and/or fever in mammals, wherein said inflammatory cytokine is capable of inducing fever in rabbits and inducing superoxide formation or respiratory burst in human neutrophils in vitro.
49. Use of the material as claimed in Claim 46 for the preparation of a pharmaceutical composition for preventing the occurrence of inflammation and/or fever in mammals, wherein said inflammatory cytokine is derived from cells which are produced by clonal replication.
50. Use of the material as claimed in Claim 46 for the preparation of a pharmaceutical composition for preventing the occurrence of inflammation and/or fever in mammals, wherein said inflammatory cytokine is derivable from animal macrophage cells that may have been incubated with a stimulator material such as might accompany an invasive stimulus.
51. Use, for the preparation of a pharmaceutical composition for treating infectious and noninfectious diseases in mammals, of a material selected from the group consisting of an inflammatory cytokine comprising a protein in purified form, an agent capable of promoting the production and/or activity of said inflammatory cytokine comprising a protein in purified form, an agent capable of mimicking the activity of said inflammatory cytokine comprising a protein in purified form, and mixtures thereof, said inflammatory cytokine comprising a protein in purified form that is anionic under physiological conditions and has an apparent molecular weight of approximately 8000 daltons as determined by SDS-PAGE and that is capable of binding to heparin, inducing localized inflammation characterized by polymorphonuclear cell infiltration when administered subcutaneously and inducing in vitro polymorphonuclear cell chemokinesis, while lacking the ability to suppress the activity of the anabolic enzyme lipoprotein lipase, cause the cytotoxicity of cachectin/TNF-sensitive cells, stimulate the blastogenesis of endotoxin-resistant C3H/HeJ thymocytes, or induce the production of cachectin/TNF by primary thioglycollate-elicited mouse macrophage cells.
52. Use of the material as claimed in Claim 51 for the preparation of a pharmaceutical composition for treating infectious and noninfectious diseases in mammals, wherein said inflammatory cytokine is anionic under physiological conditions and binds to heparin at high salt concentrations, and tends to form aggregates of high molecular weight greater than about 10⁶ daltons in low salt buffers.
53. Use of the material as claimed in Claim 51 for the preparation of a pharmaceutical composition for treating infectious and noninfectious diseases in mammals, wherein said inflammatory cytokine is capable of inducing fever in rabbits and inducing superoxide formation or respiratory burst in human neutrophils in vitro.
54. Use of the material as claimed in Claim 51 for the preparation of a pharmaceutical composition for treating infectious and noninfectious diseases in mammals, wherein said inflammatory cytokine is derivable from animal cells that may have been incubated with a stimulator material such as might accompany an invasive stimulus.

Patentansprüche

1. Ein inflammatorisches Zytokin, das ein Protein, das in der Lage ist, an Heparin zu binden, in gereinigter Form umfasst, welches, wenn es subkutan verabreicht wird, eine lokale Entzündung, die durch die Infiltration polymorphkerniger Zellen gekennzeichnet ist, induziert und das in vitro eine Chemokinese polymorphkerniger Zellen induziert, wobei die Fähigkeit fehlt, die Aktivität des anabolischen Enzyms Lipoproteinlipase zu supprimieren, die Zytotoxizität von Cachectin/TNF-empfindlichen Zellen zu verursachen, die Blastogenese von Endotoxin-resistenten C3H/HeJ Thymocyten zu stimulieren oder die Herstellung von Cachectin/TNF durch primäre Thioglycollat-induzierte Mausemakrophagenzellen zu induzieren, wobei das Protein unter physiologischen Bedingungen anionisch ist und ein apparentes Molekulargewicht von annähernd 8000 Dalton, wie über SDS-PAGE bestimmt, hat.
2. Das inflammatorische Zytokin von Anspruch 1, wobei das Zytokin bei hohen Salzkonzentrationen an Heparin bindet und dazu neigt, in Puffern mit niedrigem Salzgehalt Aggregate mit einem hohen Molekulargewicht von mehr als ungefähr 10⁶ Dalton zu bilden.

3. Das inflammatorische Zytokin von Anspruch 1, wobei das Zytokin in der Lage ist, bei Kaninchen Fieber zu induzieren und bei humanen Neutrophilen in vitro die Superoxidbildung oder einen respiratorischen burst zu induzieren.
- 5 4. Das inflammatorische Zytokin von Anspruch 1, wobei das Zytokin von tierischen Zellen, die mit einem stimulatorischen Material, das einen invasiven Stimulus begleiten könnte, inkubiert sein können, erhältlich ist.
5. Das inflammatorische Zytokin von Anspruch 1, wobei das Zytokin von Zellen, die durch klonale Vermehrung gezogen wurden, erhalten wurde.
- 10 6. Das inflammatorische Zytokin von Anspruch 1, wobei die Aminosäuresequenz im wesentlichen zu der äquivalent ist, die in Figur 10 dargestellt ist.
7. Das inflammatorische Zytokin von Anspruch 1, wobei die Aminosäuresequenz im wesentlichen zu der äquivalent ist, die in Figur 8B dargestellt ist.
- 15 8. Das inflammatorische Zytokin von Anspruch 1, wobei das Zytokin ein Peptidpaar mit Aminosäuresequenzen, die im wesentlichen zu denen äquivalent sind, die in den Figuren 8A und 8B dargestellt sind, umfaßt.
9. Das inflammatorische Zytokin von Anspruch 1, das mit einer nachweisbaren Markierung markiert ist.
- 20 10. Das inflammatorische Zytokin von Anspruch 9, wobei die Markierung ein Enzym ist.
11. Das inflammatorische Zytokin von Anspruch 10, wobei die Markierung aus der Gruppe, die aus Peroxidase, β -Glucuronidase, β -D-Glucosidase, β -D-Galactosidase, Urease, Glucose-Oxidase sowie Peroxidase, Galactose-Oxidase sowie Peroxidase, und alkalischer Phosphatase besteht, ausgewählt wird.
- 25 12. Das inflammatorische Zytokin von Anspruch 9, wobei die Markierung eine Chemikalie ist, die, wenn sie mit ultravioletttem Licht bestrahlt wird, fluoresziert.
- 30 13. Das inflammatorische Zytokin von Anspruch 12, wobei die Chemikalie aus der Gruppe ausgewählt wird, die aus Fluorescein, Rhodamin und Auramin besteht.
14. Das inflammatorische Zytokin von Anspruch 9, wobei die Markierung ein radioaktives Element ist.
- 35 15. Das inflammatorische Zytokin von Anspruch 14, wobei das radioaktive Element aus der Gruppe ausgewählt wird, die aus ^{14}C , ^{125}I , ^{131}I , ^{35}S und ^3H besteht.
- 40 16. Ein Verfahren zum Bestimmen des Vorhandenseins eines inflammatorischen Zytokins, das ein Protein, das in der Lage ist, an Heparin zu binden, in gereinigter Form umfasst, welches, wenn es subkutan verabreicht wird, eine lokale Entzündung, die durch die Infiltration polymorphkerniger Zellen gekennzeichnet ist, induziert und das in vitro eine Chemokinese polymorphkerniger Zellen induziert, wobei die Fähigkeit fehlt, die Aktivität des anabolischen Enzyms Lipoproteinlipase zu supprimieren, die Zytotoxizität von Cachectin/TNF-empfindlichen Zellen zu verursachen, die Blastogenese von Endotoxin-resistenten C3H/HeJ Thymocyten zu stimulieren oder die Herstellung von Cachectin/TNF durch primäre Thioglycolat-induzierte Mausemakrophagenzellen zu induzieren, wobei das Protein unter physiologischen Bedingungen anionisch ist und ein apparentes Molekulargewicht von annähernd 6000 Dalton, wie über SDS-PAGE bestimmt, hat, wobei das inflammatorische Zytokin bestimmt wird durch:
 - 50 A. Herstellen von wenigstens einer Probe des inflammatorischen Zytokins von tierischen Zellen, die einer entsprechenden Anzahl von bestimmten bekannten invasiven Stimuli ausgesetzt wurden;
 - B. Herstellen wenigstens eines entsprechenden Antikörpers oder Bindepartners, der gegen die inflammatorischen Zytokinproben gerichtet ist;
 - C. Anbringen einer nachweisbaren Markierung auf einem Material, das aus der Gruppe ausgewählt wird, die aus den inflammatorischen Zytokinproben und dem Antikörper oder den Bindepartnern dafür besteht;
 - 55 D. Immobilisieren eines Materials, das aus der Gruppe ausgewählt wird, die aus dem Material von Stufe C, das nicht markiert ist, besteht und einer biologischen Probe aus einem Säugetier, in der das inflammatorische Zytokin vermutet wird, auf einem geeigneten Träger;
 - E. Anbringen des markierten Materials aus Stufe C in Kontakt mit der biologischen Probe und in Kontakt mit dem immobilisierten Material;

F. Abtrennen des Materials aus Stufe C, das an das immobilisierte Material gebunden ist, von dem Material aus Stufe C, das nicht an das immobilisierte Material gebunden ist; und

G. Untersuchen des gebundenen Materials auf das Vorhandensein des markierten Materials.

- 5 17. Ein Verfahren zum Bestimmen der Bindestellen für ein inflammatorisches Zytokin, umfassend ein Protein in gereinigter Form, das unter physiologischen Bedingungen anionisch ist und ein apparentes Molekulargewicht von annähernd 8000 Dalton, wie über SDS-PAGE bestimmt, hat, und das in der Lage ist, an Heparin zu binden, in gereinigter Form umfasst, welches, wenn es subkutan verabreicht wird, eine lokale Entzündung, die durch die Infiltration polymorphkerniger Zellen gekennzeichnet ist, induziert und das in vitro eine Chemokinese polymorphkerniger Zellen induziert, wobei die Fähigkeit fehlt, die Aktivität des anabolischen Enzyms Lipoproteinlipase zu
10 supprimieren, die Zytotoxizität von Cachectin/TNF-empfindlichen Zellen zu verursachen, die Blastogenese von Endotoxin-resistenten C3H/HeJ Thymocyten zu stimulieren oder die Herstellung von Cachectin/TNF durch primäre Thioglycolat-induzierte Mausmakrophagenzellen zu induzieren, wobei die Bindestellen für das inflammatorische Zytokin bestimmt werden durch:
15
 - A. Herstellen wenigstens einer Probe des inflammatorischen Zytokins aus einer entsprechenden Anzahl von bestimmten bekannten invasiven Stimuli;
 - B. Anbringen einer nachweisbaren Markierung an der inflammatorischen Zytokinprobe;
 - 20 C. Anbringen der markierten inflammatorischen Zytokinprobe in Kontakt mit einer biologischen Probe aus einem Säugetier, in der Bindestellen für das Zytokin vermutet werden; und
 - D. Untersuchen der biologischen Probe in Bindungsstudien auf das Vorhandensein der markierten inflammatorischen Zytokinprobe.
- 25 18. Das Verfahren von Anspruch 16, das ein Verfahren zum Bestimmen des Vorhandenseins eines inflammatorischen Zytokins, das mit einem gegebenen invasiven Stimulus in Säugetieren verbunden ist, umfaßt.
19. Das Verfahren von Anspruch 16, das ein Verfahren zur Bestimmung des Vorhandenseins von invasiven oder idiopathischen Stimuli in Säugetieren umfaßt.
- 30 20. Das Verfahren von Anspruch 16, wobei der invasive Stimulus eine Infektion ist.
21. Das Verfahren von Anspruch 16, wobei der invasive Stimulus ausgewählt wird aus der Gruppe, die aus bakterieller Infektion, viraler Infektion, protozoaler Infektion, tumorösen Säugetierzellen und Toxinen besteht.
- 35 22. Das Verfahren von Anspruch 16, wobei das inflammatorische Zytokin hergestellt wird durch:
 - A. Isolieren einer Kolonie von Säugetierzellen;
 - B. Inkubieren der Zellen mit dem Stimulormaterial über einen Zeitraum, der für das Stimulormaterial ausreichend ist, um die Zellen zu stimulieren, daß sie inflammatorisches Zytokin herstellen; und
40 C. Isolieren des inflammatorischen Zytokins von den Zellen.
23. Das Verfahren von Anspruch 22, wobei das Stimulormaterial ein Endotoxin umfaßt.
- 45 24. Das Verfahren von Anspruch 23, wobei das Endotoxin Lipopolysaccharid umfaßt.
25. Ein Verfahren zur Untersuchung der Fähigkeit einer Droge, die Herstellung und/oder Aktivität eines inflammatorischen Zytokins zu modulieren, umfassend ein Protein in gereinigter Form, das in der Lage ist, mit einem Rezeptor für das inflammatorische Zytokin auf Zellen in einem Säugetierkörper zu reagieren, das umfaßt das Kultivieren einer Kolonie von Testzellen, die den Rezeptor tragen, in einem Wachstumsmedium, das das inflammatorische Zytokin enthält, das Zugabe der Droge im Test und danach das Messen der Reaktivität der Droge mit dem Rezeptor auf der Kolonie der Testzellen, wobei das inflammatorische Zytokin ein Protein, das in der Lage ist, an Heparin zu binden, in gereinigter Form umfasst, welches, wenn es subkutan verabreicht wird, eine lokale Entzündung, die durch die Infiltration polymorphkerniger Zellen gekennzeichnet ist, induziert und das in vitro eine Chemokinese polymorphkerniger Zellen induziert, wobei die Fähigkeit fehlt, die Aktivität des anabolischen Enzyms Lipoproteinlipase zu supprimieren, die Zytotoxizität von Cachectin/TNF-empfindlichen Zellen zu verursachen, die Blastogenese von Endotoxin-resistenten C3H/HeJ Thymocyten zu stimulieren oder die Herstellung von Cachectin/TNF durch primäre Thioglycolat-induzierte Mausmakrophagenzellen zu induzieren, wobei das Protein unter physiologischen Bedingungen anionisch ist und ein apparentes Molekulargewicht von annähernd 8000 Dalton, wie
50
55

über SDS-PAGE bestimmt, hat.

26. Das Verfahren von Anspruch 25, wobei das inflammatorische Zytokin unter physiologischen Bedingungen anionisch ist und bei hohen Salzkonzentrationen an Heparin bindet, und das dazu neigt, in Puffern mit niedrigem Salzgehalt Aggregate mit einem hohen Molekulargewicht von mehr als ungefähr 10^6 Dalton zu bilden.
27. Das Verfahren von Anspruch 25, bei Kaninchen Fieber zu induzieren und bei humanen Neutrophilen in vitro die Superoxidbildung oder einen respiratorischen burst zu induzieren.
28. Das Verfahren von Anspruch 25, wobei das inflammatorische Zytokin von tierischen Zellen, die mit einem stimulatorischen Material, das einen invasiven Stimulus begleiten könnte, inkubiert sein können, erhältlich ist.
29. Das Verfahren von Anspruch 25, wobei das inflammatorische Zytokin von Zellen, die durch klonale Vermehrung gezogen wurden, erhalten wurde.
30. Ein Untersuchungssystem für das Screening von Drogen und anderen Mitteln auf die Fähigkeit, die Herstellung und/oder Aktivität eines inflammatorischen Zytokins zu modulieren, umfassend eine meßbare zelluläre Testkolonie, die mit einem inflammatorischen Zytokin beimpft wurde, das ein Protein in gereinigter Form umfaßt, das in der Lage ist, an Heparin zu binden, welches, wenn es subkutan verabreicht wird, eine lokale Entzündung, die durch die Infiltration polymorphkerniger Zellen gekennzeichnet ist, induziert und das in vitro eine Chemokinese polymorphkerniger Zellen induziert, wobei die Fähigkeit fehlt, die Aktivität des anabolischen Enzyms Lipoproteinlipase zu supprimieren, die Zytotoxizität von Cachectin/TNF-empfindlichen Zellen zu verursachen, die Blastogenese von Endotoxin-resistenten C3H/HeJ Thymocyten zu stimulieren oder die Herstellung von Cachectin/TNF durch primäre Thioglycolat-induzierte Mausemakrophagenzellen zu induzieren, wobei das Protein unter physiologischen Bedingungen anionisch ist und ein apparentes Molekulargewicht von annähernd 8000 Dalton, wie über SDS-PAGE bestimmt, hat.
31. Das Untersuchungssystem von Anspruch 30, wobei das Zytokin unter physiologischen Bedingungen anionisch ist und an Heparin bei hohen Salzkonzentrationen bindet und das dazu neigt, in Puffern mit einem niedrigen Salzgehalt Aggregate mit einem hohen Molekulargewicht von mehr als ungefähr 10^6 Dalton zu bilden.
32. Das Untersuchungssystem von Anspruch 30, wobei das Zytokin in der Lage ist, bei Kaninchen Fieber zu induzieren und bei humanen Neutrophilen in vitro die Superoxidbildung oder einen respiratorischen burst zu induzieren.
33. Das Untersuchungssystem von Anspruch 30, wobei das inflammatorische Zytokin von tierischen Zellen, die mit einem stimulatorischen Material, das einen invasiven Stimulus begleiten könnte, inkubiert sein können, erhältlich ist.
34. Das Untersuchungssystem von Anspruch 30, wobei das inflammatorische Zytokin von Zellen, die durch klonale Vermehrung gezogen wurden, erhalten wurde.
35. Ein Testkit für den Nachweis eines inflammatorischen Zytokins in einem Serum oder einem wäßrigen Medium, umfassend:
 - A. eine vorbestimmte Menge von wenigstens einer markierten immunchemisch reaktiven Komponente, die durch die direkte oder indirekte Anbringung eines inflammatorischen Zytokins oder eines spezifischen Bindepartners dazu an eine nachweisbare Markierung erhalten wird, wobei das inflammatorische Zytokin ein Protein umfaßt, das unter physiologischen Bedingungen anionisch ist und ein apparentes Molekulargewicht von annähernd 8000 Dalton, wie über SDS-PAGE bestimmt, hat, und das in der Lage ist, an Heparin zu binden, welches, wenn es subkutan verabreicht wird, eine lokale Entzündung, die durch die Infiltration polymorphkerniger Zellen gekennzeichnet ist, induziert und das in vitro eine Chemokinese polymorphkerniger Zellen induziert, wobei die Fähigkeit fehlt, die Aktivität des anabolischen Enzyms Lipoproteinlipase zu supprimieren, die Zytotoxizität von Cachectin/TNF-empfindlichen Zellen zu verursachen, die Blastogenese von Endotoxin-resistenten C3H/HeJ Thymocyten zu stimulieren oder die Herstellung von Cachectin/TNF durch primäre Thioglycolat-induzierte Mausemakrophagenzellen zu induzieren,
 - B. anderen Reagenzien; und
 - C. Anweisungen für die Verwendung des Kits.

36. Das Testkit von Anspruch 35, wobei das inflammatorische Zytokin unter physiologischen Bedingungen anionisch ist und an Heparin bei hohen Salzkonzentrationen bindet, und das dazu neigt, in Puffern mit niedrigem Salzgehalt Aggregate mit einem hohen Molekulargewicht von mehr als ungefähr 10^6 Dalton zu bilden.
- 5 37. Das Testkit von Anspruch 35, wobei das inflammatorische Zytokin in der Lage ist, bei Kaninchen Fieber zu induzieren und bei humanen Neutrophilen in vitro die Superoxidbildung oder einen respiratorischen burst zu induzieren.
38. Das Testkit von Anspruch 35, wobei das inflammatorische Zytokin von tierischen Zellen, die mit einem stimulatorischen Material, das einen invasiven Stimulus begleiten könnte, inkubiert sein können, erhältlich ist.
- 10 39. Das Testkit von Anspruch 35, wobei das Zytokin von Zellen, die durch klonale Vermehrung gezogen wurden, erhältlich ist.
- 15 40. Das Testkit von Anspruch 35, wobei die Markierung ein Enzym ist.
41. Die Verwendung eines Materials für die Herstellung einer pharmazeutischen Zusammensetzung für die Behandlung von Entzündung und/oder Fieber bei Säugetieren, das ausgewählt wird aus der Gruppe, die besteht aus einem Antikörper gegen ein inflammatorisches Zytokin, umfassend ein Protein in gereinigter Form, einem Mittel, das in der Lage ist, die Herstellung des inflammatorischen Zytokins zu inhibieren, umfassend ein Protein in gereinigter Form, ein Mittel, das kein Antikörper gegen das inflammatorische Zytokin ist, umfassend ein Protein in gereinigter Form, das in der Lage ist, als ein Antagonist gegenüber dem inflammatorischen Zytokin zu wirken, wobei das inflammatorische Zytokin ein Protein in einer gereinigten Form umfaßt, das unter physiologischen Bedingungen anionisch ist und ein apparentes Molekulargewicht von annähernd 8000 Dalton, wie über SDS-PAGE bestimmt, hat, und das in der Lage ist, an Heparin zu binden, welches, wenn es subkutan verabreicht wird, eine lokale Entzündung, die durch die Infiltration polymorphkerniger Zellen gekennzeichnet ist, induziert und das in vitro eine Chemokinese polymorphkerniger Zellen induziert, wobei die Fähigkeit fehlt, die Aktivität des anabolischen Enzyms Lipoproteinlipase zu supprimieren, die Zytotoxizität von Cachectin/TNF-empfindlichen Zellen zu verursachen, die Blastogenese von Endotoxin-resistenten C3H/HeJ Thymocyten zu stimulieren oder die Herstellung von Cachectin/TNF durch primäre Thioglycolat-induzierte Mausmakrophagenzellen zu induzieren.
- 20 42. Die Verwendung des Materials wie in Anspruch 41 beansprucht für die Herstellung einer pharmazeutischen Zusammensetzung für die Behandlung von Entzündung und/oder Fieber bei Säugetieren, gekennzeichnet dadurch, daß das inflammatorische Zytokin bei hohen Salzkonzentrationen an Heparin bindet und daß es dazu neigt, in Puffern mit einem niedrigen Salzgehalt Aggregate mit einem hohen Molekulargewicht von mehr als ungefähr 10^6 Dalton zu bilden.
- 25 43. Die Verwendung des Materials wie in Anspruch 41 beansprucht für die Herstellung einer pharmazeutischen Zusammensetzung für die Behandlung von Entzündung und/oder Fieber in Säugetieren, wobei das Zytokin in der Lage ist, bei Kaninchen Fieber zu induzieren und bei humanen Neutrophilen in vitro die Superoxidbildung oder einen respiratorischen burst zu induzieren.
- 30 44. Die Verwendung des Materials wie in Anspruch 41 beansprucht für die Herstellung einer pharmazeutischen Zusammensetzung für die Behandlung von Entzündung und/oder Fieber bei Säugetieren, wobei das inflammatorische Zytokin von tierischen Zellen, die mit einem stimulatorischen Material, das einen invasiven Stimulus begleiten könnte, inkubiert sein können, erhältlich ist.
- 35 45. Die Verwendung des Materials wie in Anspruch 41 beansprucht für die Herstellung einer pharmazeutischen Zusammensetzung für die Behandlung von Entzündung und/oder Fieber in Säugetieren, wobei das inflammatorische Zytokin von Zellen, die durch klonale Vermehrung gezogen wurden, erhalten wurde.
- 40 46. Die Verwendung eines Materials für die Herstellung einer pharmazeutischen Zusammensetzung zur Verhinderung des Auftretens von Entzündung und/oder Fieber bei Säugetieren, das ausgewählt wird aus der Gruppe, die besteht aus einem Antikörper gegen ein inflammatorisches Zytokin, umfassend ein Protein in gereinigter Form, einem Mittel, das in der Lage ist, die Herstellung des inflammatorischen Zytokins zu inhibieren, umfassend ein Protein in gereinigter Form, ein Mittel, das kein Antikörper gegen das inflammatorische Zytokin ist, umfassend ein Protein in gereinigter Form, das in der Lage ist, der Aktivität des inflammatorischen Zytokins entgegenzuwirken, und Mischungen davon, in einer Menge, die wirksam ist, den Beginn der Entzündung und/oder des Fiebers, abzuwenden, wobei das inflammatorische Zytokin ein Protein in einer gereinigten Form umfaßt, das unter physiolo-
- 45 50 55

- gischen Bedingungen anionisch ist und ein apparentes Molekulargewicht von annähernd 8000 Dalton, wie über SDS-PAGE bestimmt, hat, und das in der Lage ist, an Heparin zu binden, welches, wenn es subkutan verabreicht wird, eine lokale Entzündung, die durch die Infiltration polymorphkerniger Zellen gekennzeichnet ist, induziert und das in vitro eine Chemokinese polymorphkerniger Zellen induziert, wobei die Fähigkeit fehlt, die Aktivität des anabolischen Enzyms Lipoproteinlipase zu supprimieren, die Zytotoxizität von Cachectin/TNF-empfindlichen Zellen zu verursachen, die Blastogenese von Endotoxin-resistenten C3H/HeJ Thymocyten zu stimulieren oder die Herstellung von Cachectin/TNF durch primäre Thioglycolat-induzierte Mausmakrophagenzellen zu induzieren.
47. Die Verwendung des Materials wie in Anspruch 46 beansprucht für die Herstellung einer pharmazeutischen Zusammensetzung zur Verhinderung des Auftretens von Entzündung und/oder Fieber bei Säugetieren, wobei das inflammatorische Zytokin unter physiologischen Bedingungen anionisch ist und bei hohen Salzkonzentrationen an Heparin bindet und das dazu neigt, in Puffern mit einem niedrigen Salzgehalt Aggregate mit einem hohen Molekulargewicht von mehr als etwa 10^6 Dalton zu bilden.
48. Die Verwendung des Materials wie in Anspruch 46 beansprucht für die Herstellung einer pharmazeutischen Zusammensetzung zum Verhinderung des Auftretens von Entzündung und/oder Fieber bei Säugetieren, wobei das inflammatorische Zytokin in der Lage ist, bei Kaninchen Fieber zu induzieren und bei humanen Neutrophilen in vitro die Superoxidbildung oder einen respiratorischen burst zu induzieren.
49. Die Verwendung des Materials wie in Anspruch 46 beansprucht für die Herstellung einer pharmazeutischen Zusammensetzung zur Verhinderung des Auftretens von Entzündung und/oder Fieber bei Säugetieren, wobei das inflammatorische Zytokin von Zellen, die durch klonale Vermehrung gezogen wurden, erhalten wurde.
50. Die Verwendung des Materials wie in Anspruch 46 beansprucht für die Herstellung einer pharmazeutischen Zusammensetzung zur Verhinderung des Auftretens von Entzündung und/oder Fieber bei Säugetieren, wobei das inflammatorische Zytokin von tierischen Zellen, die mit einem stimulatorischen Material, das einen invasiven Stimulus begleiten könnte, inkubiert sein können, erhältlich ist.
51. Die Verwendung eines Materials für die Herstellung einer pharmazeutischen Zusammensetzung zum Behandeln von infektiösen und nichtinfektiösen Erkrankungen bei Säugetieren, das aus der Gruppe, die besteht aus einem inflammatorischen Zytokin, umfassend ein Protein in gereinigter Form, einem Mittel, das in der Lage ist, die Herstellung und/oder Aktivität des inflammatorischen Zytokins, das ein Protein in gereinigter Form umfaßt, zu fördern, einem Mittel, das in der Lage ist, die Aktivität des inflammatorischen Zytokins, das ein Protein in gereinigter Form umfaßt, nachzuahmen, und Mischungen davon, ausgewählt wird, wobei das inflammatorische Zytokin ein Protein in einer gereinigten Form umfaßt, das unter physiologischen Bedingungen anionisch ist und ein apparentes Molekulargewicht von annähernd 8000 Dalton, wie über SDS-PAGE bestimmt, hat, und das in der Lage ist, an Heparin zu binden, welches, wenn es subkutan verabreicht wird, eine lokale Entzündung, die durch die Infiltration polymorphkerniger Zellen gekennzeichnet ist, induziert und das in vitro eine Chemokinese polymorphkerniger Zellen induziert, wobei die Fähigkeit fehlt, die Aktivität des anabolischen Enzyms Lipoproteinlipase zu supprimieren, die Zytotoxizität von Cachectin/TNF-empfindlichen Zellen zu verursachen, die Blastogenese von Endotoxin-resistenten C3H/HeJ Thymocyten zu stimulieren oder die Herstellung von Cachectin/TNF durch primäre Thioglycolat-induzierte Mausmakrophagenzellen zu induzieren.
52. Die Verwendung des Materials wie in Anspruch 51 beansprucht für die Herstellung einer pharmazeutischen Zusammensetzung zum Behandeln von infektiösen und nichtinfektiösen Erkrankungen bei Säugetieren, wobei das inflammatorische Zytokin unter physiologischen Bedingungen anionisch ist und bei hohen Salzkonzentrationen an Heparin bindet und das dazu neigt, in Puffern mit einem niedrigen Salzgehalt Aggregate mit einem hohen Molekulargewicht von mehr als etwa 10^6 Dalton zu bilden.
53. Die Verwendung des Materials wie in Anspruch 51 beansprucht für die Herstellung einer pharmazeutischen Zusammensetzung für die Behandlung von infektiösen und nichtinfektiösen Erkrankungen bei Säugetieren, wobei das inflammatorische Zytokin in der Lage ist, bei Kaninchen Fieber zu induzieren und bei humanen Neutrophilen in vitro die Superoxidbildung oder einen respiratorischen burst zu induzieren.
54. Die Verwendung des Material wie in Anspruch 51 beansprucht für die Herstellung einer pharmazeutischen Zusammensetzung für die Behandlung von infektiösen und nichtinfektiösen Erkrankungen bei Säugetieren, wobei das inflammatorische Zytokin von tierischen Zellen, die mit einem stimulatorischen Material, das einen invasiven Stimulus begleiten könnte, inkubiert sein können, erhältlich ist.

Revendications

1. Cytokine inflammatoire comprenant une protéine sous une forme purifiée apte à se fixer à l'héparine, induisant une inflammation localisée caractérisée par une infiltration de cellules polymorphonucléaires lorsqu'elle est administrée par la voie sous-cutanée et induisant une chimiocinésie de cellules polymorphonucléaires in vitro, tout en étant incapable de supprimer l'activité de l'enzyme anabolique lipoprotéine lipase, de présenter une cytotoxicité à l'encontre de cellules sensibles à la cachectine/TNF (facteur nécrosant des tumeurs), de stimuler la blastogenèse de thymocytes C3H/HeJ résistants aux endotoxines, ou d'induire la production de cachectine/TNF par des cellules primaires de macrophages de souris stimulées au thioglycolate, ladite protéine étant anionique dans des conditions physiologiques et possédant un poids moléculaire apparent d'environ 8000 Daltons comme déterminé par SDS-PAGE.
2. Cytokine inflammatoire selon la revendication 1 dans laquelle ladite cytokine se fixe à l'héparine aux fortes concentrations salines et a tendance à former des agrégats de haut poids moléculaire d'une valeur supérieure à environ 10^6 Daltons dans des tampons à faible concentration saline.
3. Cytokine inflammatoire selon la revendication 1 dans laquelle ladite cytokine est capable d'induire la fièvre chez des lapins et d'induire la formation de superoxyde ou un stress oxydant dans des neutrophiles humains in vitro.
4. Cytokine inflammatoire selon la revendication 1 dans laquelle ladite cytokine est susceptible d'être obtenue à partir de cellules animales qui ont pu être incubées avec un produit stimulant pouvant accompagner un stimulus invasif.
5. Cytokine inflammatoire selon la revendication 1 dans laquelle ladite cytokine est obtenue à partir de cellules qui sont produites par réplique clonale.
6. Cytokine inflammatoire selon la revendication 1 présentant la séquence d'acides aminés sensiblement équivalente à celle présentée à la Figure 10.
7. Cytokine inflammatoire selon la revendication 1 présentant la séquence d'acides aminés sensiblement équivalente à celle présentée à la Figure 8B.
8. Cytokine inflammatoire selon la revendication 1 dans laquelle ladite cytokine comprend un doublet peptidique présentant les séquences d'acides aminés sensiblement équivalentes à celles présentées aux Figures 8A et 8B.
9. Cytokine inflammatoire selon la revendication 1 marquée avec un marqueur détectable.
10. Cytokine inflammatoire selon la revendication 9 dans laquelle le marqueur est une enzyme.
11. Cytokine inflammatoire selon la revendication 10 dans laquelle le marqueur est choisi dans le groupe constitué de la peroxydase, la β -glucuronidase, la β -D-glucosidase, la β -D-galactosidase, l'uréase, la glucose oxydase associée à la peroxydase, la glucose oxydase associée à la peroxydase et à la phosphatase alcaline.
12. Cytokine inflammatoire selon la revendication 9 dans laquelle le marqueur est un produit chimique qui est fluorescent lorsqu'il est exposé à la lumière ultraviolette.
13. Cytokine inflammatoire selon la revendication 12 dans laquelle le produit chimique est choisi dans le groupe constitué de la fluorescéine, la rhodamine et l'auramine.
14. Cytokine inflammatoire selon la revendication 9 dans laquelle le marqueur est un radioélément.
15. Cytokine inflammatoire selon la revendication 14 dans laquelle le radioélément est choisi dans le groupe constitué du ^{14}C , de l' ^{125}I , de l' ^{131}I , du ^{35}S et du ^3H .
16. Méthode de détermination de la présence d'une cytokine inflammatoire comprenant une protéine sous une forme purifiée apte à se fixer à l'héparine, induisant une inflammation localisée caractérisée par une infiltration de cellules polymorphonucléaires lorsqu'elle est administrée par la voie sous-cutanée et induisant une chimiocinésie de cellules polymorphonucléaires in vitro, tout en étant incapable de supprimer l'activité de l'enzyme anabolique lipoprotéine lipase, de présenter une cytotoxicité à l'encontre de cellules sensibles à la cachectine/TNF (facteur né-

crosant des tumeurs), de stimuler la blastogénèse de thymocytes C3H/HeJ résistants aux endotoxines, ou d'induire la production de cachectine/TNF par des cellules primaires de macrophages de souris stimulées au thioglycolate, ladite cytokine étant anionique dans des conditions physiologiques et possède un poids moléculaire apparent d'environ 8000 Daltons comme déterminé par SDS-PAGE, ladite cytokine inflammatoire étant mesurée par la méthode comprenant les étapes consistant à :

5

- A. préparer au moins un échantillon de ladite cytokine inflammatoire à partir de cellules animales qui ont été exposées à un nombre correspondant de stimuli invasifs distincts connus;
- 10 B. préparer au moins un anticorps correspondant ou un partenaire de fixation dirigé contre lesdits échantillons de cytokine inflammatoire;
- C. placer un marqueur détectable sur un produit choisi dans le groupe constitué desdits échantillons de cytokine inflammatoire et desdits anticorps ou partenaires de fixation dirigés contre ces derniers;
- D. immobiliser un produit choisi dans le groupe constitué du produit de l'étape C qui n'est pas marqué et d'un échantillon biologique provenant d'un mammifère dans lequel est censé se trouver ladite cytokine inflammatoire, sur un substrat approprié ;
- 15 E. mettre le produit marqué de l'étape C en contact avec ledit échantillon biologique et en contact avec le produit immobilisé;
- F. séparer le produit de l'étape C qui est fixé audit produit immobilisé du produit de l'étape C qui ne s'est pas fixé audit produit immobilisé; et
- 20 G. détecter la présence dudit produit marqué dans le produit fixé.

20

17. Méthode de détection de sites de fixation pour une cytokine inflammatoire comprenant une protéine sous forme purifiée qui est anionique dans des conditions physiologiques et présente un poids moléculaire apparent d'environ 8000 Daltons comme déterminé par SDS-PAGE et qui est apte à se fixer à l'héparine, induisant une inflammation localisée caractérisée par une infiltration de cellules polymorphonucléaires lorsqu'elle est administrée par la voie sous-cutanée et induisant une chimiocinésie de cellules polymorphonucléaires in vitro, tout en étant incapable de supprimer l'activité de l'enzyme anabolique lipoprotéine lipase, de présenter une cytotoxicité à l'encontre de cellules sensibles à la cachectine/TNF (facteur nécrosant des tumeurs), de stimuler la blastogénèse de thymocytes C3H/HeJ résistants aux endotoxines, ou d'induire la production de cachectine/TNF par des cellules primaires de macrophages de souris stimulées au thioglycolate, dans laquelle les sites de fixation pour ladite cytokine inflammatoire sont détectés par Une méthode comprenant les étapes consistant à :

25

30

- A. préparer au moins un échantillon de ladite cytokine inflammatoire à partir d'un nombre correspondant de stimuli invasifs distincts connus;
- 35 B. placer un marqueur détectable sur ledit échantillon de cytokine inflammatoire;
- C. mettre en contact l'échantillon de cytokine inflammatoire marqué avec un échantillon biologique provenant d'un mammifère dans lequel sont censés se trouver les sites de fixation pour ladite cytokine ; et
- D. détecter la présence dans ledit échantillon biologique lors d'études de fixation dudit échantillon de cytokine inflammatoire marqué.

40

18. Méthode selon la revendication 16 comprenant une méthode de détection de la présence d'une cytokine inflammatoire associée à un stimulus invasif déterminé chez les mammifères.

19. Méthode selon la revendication 16 comprenant une méthode de détection de la présence de stimuli invasifs ou idiopathiques chez des mammifères.

45

20. Méthode selon la revendication 16 dans laquelle ledit stimulus invasif est une infection.

21. Méthode selon la revendication 16 dans laquelle ledit stimulus invasif est choisi dans le groupe constitué par une infection bactérienne, une infection virale, une infection par des protozoaires, des cellules tumorales de mammifères et des toxines.

50

22. Méthode selon la revendication 16 dans laquelle ladite cytokine inflammatoire est préparée par une méthode comprenant les étapes consistant à :

55

- A. isoler une colonie de cellules de mammifères;
- B. incuber lesdites cellules avec ledit produit stimulant pendant une période de temps suffisante permettant audit produit stimulant d'induire lesdites cellules à produire ladite cytokine inflammatoire; et

C. isoler ladite cytokine inflammatoire desdites cellules.

23. Méthode selon la revendication 22 dans laquelle ledit produit stimulant comprend une endotoxine.
- 5 24. Méthode selon la revendication 23 dans laquelle ladite endotoxine comprend un lipopolysaccharide.
- 10 25. Méthode de test de l'aptitude d'un médicament à moduler la production et/ou l'activité d'une cytokine inflammatoire comprenant une protéine sous forme purifiée capable de réagir avec un récepteur de la cytokine inflammatoire sur des cellules dans un corps de mammifère qui comprend les étapes consistant à cultiver une colonie de cellules d'essai qui possède ledit récepteur dans un milieu de culture contenant la cytokine inflammatoire, à ajouter le médicament à tester et à déterminer ensuite la réactivité dudit médicament avec ledit récepteur sur ladite colonie de cellules d'essai, ladite cytokine inflammatoire comprenant un produit protéique apte à se fixer à l'héparine, induisant une inflammation localisée caractérisée par une infiltration de cellules polymorphonucléaires lorsqu'il est administré par la voie sous-cutanée et induisant une chimiocinésie de cellules polymorphonucléaires in vitro, tout en étant incapable de supprimer l'activité de l'enzyme anabolique lipoprotéine lipase, de présenter une cytotoxicité à l'encontre de cellules sensibles à la cachectine/TNF (facteur nécrosant des tumeurs), de stimuler la blastogénèse de thymocytes C3H/HeJ résistants aux endotoxines, ou d'induire la production de cachectine/TNF par des cellules primaires de macrophages de souris stimulées au thioglycolate, ledit produit protéique étant anionique dans des conditions physiologiques et possèdent un poids moléculaire apparent d'environ 8000 Daltons comme déterminé par SDS-PAGE.
- 15 26. Méthode selon la revendication 25 dans laquelle ladite cytokine inflammatoire est anionique dans les conditions physiologiques et se fixe à l'héparine aux fortes concentrations salines et a tendance à former des agrégats de haut poids moléculaire d'une valeur supérieure à environ 10^6 Daltons dans des tampons à faible concentration saline.
- 25 27. Méthode selon la revendication 25 dans laquelle ladite cytokine inflammatoire est capable d'induire la fièvre chez des lapins et d'induire la formation de superoxyde ou un stress oxydant dans des neutrophiles humains in vitro.
- 30 28. Méthode selon la revendication 25 dans laquelle ladite cytokine inflammatoire est susceptible d'être obtenue à partir de cellules animales qui ont pu être incubées avec un produit stimulant pouvant accompagner un stimulus invasif.
- 35 29. Méthode selon la revendication 25 dans laquelle ladite cytokine inflammatoire est obtenue à partir de cellules qui sont produites par réplication clonale.
- 40 30. Système de test pour la détermination dans des médicaments et autres agents de l'aptitude à moduler la production et/ou l'activité d'une cytokine inflammatoire comprenant une colonie de cellules d'essai observable inoculée avec une cytokine inflammatoire comprenant une protéine sous une forme purifiée apte à se fixer à l'héparine, induisant une inflammation localisée caractérisée par une infiltration de cellules polymorphonucléaires lorsqu'elle est administrée par la voie sous-cutanée et induisant une chimiocinésie de cellules polymorphonucléaires in vitro, tout en étant incapable de supprimer l'activité de l'enzyme anabolique lipoprotéine lipase, de présenter une cytotoxicité à l'encontre de cellules sensibles à la cachectine/TNF (facteur nécrosant des tumeurs), de stimuler la blastogénèse de thymocytes C3H/HeJ résistants aux endotoxines, ou d'induire la production de cachectine/TNF par des cellules primaires de macrophages de souris stimulées au thioglycolate, ladite protéine étant anionique dans des conditions physiologiques et possèdent un poids moléculaire apparent d'environ 8000 Daltons comme déterminé par SDS-PAGE.
- 45 31. Système de test selon la revendication 30 dans lequel ladite cytokine est anionique dans des conditions physiologiques et se fixe à l'héparine aux fortes concentrations salines et a tendance à former des agrégats de haut poids moléculaire d'une valeur supérieure à environ 10^6 Daltons dans des tampons à faible concentration saline.
- 50 32. Système de test selon la revendication 30 dans lequel ladite cytokine est capable d'induire la fièvre chez des lapins et d'induire la formation de superoxyde ou un stress oxydant dans des neutrophiles humains in vitro.
- 55 33. Système de test selon la revendication 30 dans lequel ladite cytokine inflammatoire est susceptible d'être obtenue à partir de cellules animales qui ont pu être incubées avec un produit stimulant pouvant accompagner un stimulus invasif.

34. Système de test selon la revendication 30 dans lequel ladite cytokine inflammatoire est obtenue à partir de cellules qui sont produites par réplication clonale.
- 5 35. Trousse de test pour déterminer la présence d'une cytokine inflammatoire dans un sérum ou un milieu aqueux, comprenant:
- 10 A. Une quantité prédéterminée d'au moins un composé marqué réactif d'un point de vue immunochimique obtenu par la fixation directe ou indirecte d'une cytokine inflammatoire, ou d'un partenaire de fixation spécifique dirigés contre cette dernière, à un marqueur détectable, ladite cytokine inflammatoire comprenant une protéine qui est anionique dans des conditions physiologiques et présente un poids moléculaire apparent d'environ 8000 Daltons comme déterminé par SDS-PAGE et qui est apte à se fixer à l'héparine, induisant une inflammation localisée caractérisée par une infiltration de cellules polymorphonucléaires lorsqu'elle est administrée par la voie sous-cutanée et induisant une chimiocinésie de cellules polymorphonucléaires in vitro, tout en étant incapable de supprimer l'activité de l'enzyme anabolique lipoprotéine lipase, de présenter une cytotoxicité à l'encontre de cellules sensibles à la cachectine/TNF (facteur nécrosant des tumeurs), de stimuler la blastogénèse de thymocytes C3H/HeJ résistants aux endotoxines, ou d'induire la production de cachectine/TNF par des cellules primaires de macrophages de souris stimulées au thioglycolate,
- 15 B. d'autres réactifs; et
- 20 C. des consignes d'utilisation de ladite trousse.
36. Trousse de test selon la revendication 35 dans laquelle ladite cytokine inflammatoire est anionique dans les conditions physiologiques et se fixe à l'héparine aux fortes concentrations salines et a tendance à former des agrégats de haut poids moléculaire d'une valeur supérieure à environ 10^6 Daltons dans des tampons à faible concentration saline.
- 25 37. Trousse de test selon la revendication 35 dans laquelle ladite cytokine inflammatoire est capable d'induire la fièvre chez des lapins et d'induire la formation de superoxyde ou un stress oxydant dans des neutrophiles humains in vitro.
- 30 38. Trousse de test selon la revendication 35 dans laquelle ladite cytokine inflammatoire est susceptible d'être obtenue à partir de cellules animales qui ont pu être incubées avec un produit stimulant pouvant accompagner un stimulus invasif.
- 35 39. Trousse de test selon la revendication 35 dans laquelle ladite cytokine est susceptible d'être obtenue à partir de cellules qui sont produites par réplication clonale.
- 40 40. Trousse de test selon la revendication 35 dans laquelle le marqueur est une enzyme.
41. Utilisation, pour la préparation d'une composition pharmaceutique destinée au traitement de l'inflammation et/ou de la fièvre chez des mammifères, d'un produit choisi dans le groupe constitué par un anticorps dirigé contre une cytokine inflammatoire comprenant une protéine sous forme purifiée, un agent capable d'inhiber la production de ladite cytokine inflammatoire comprenant une protéine sous forme purifiée, un agent distinct d'un anticorps dirigé contre ladite cytokine inflammatoire comprenant une protéine sous une forme purifiée capable d'agir en tant qu'antagoniste de ladite cytokine inflammatoire, ladite cytokine inflammatoire comprenant une protéine sous forme purifiée qui est anionique dans des conditions physiologiques et présente un poids moléculaire apparent d'environ 8000 Daltons comme déterminé par SDS-PAGE et qui est apte à se fixer à l'héparine, induisant une inflammation localisée caractérisée par une infiltration de cellules polymorphonucléaires lorsqu'elle est administrée par la voie sous-cutanée et induisant une chimiocinésie de cellules polymorphonucléaires in vitro, tout en étant incapable de supprimer l'activité de l'enzyme anabolique lipoprotéine lipase, de présenter une cytotoxicité à l'encontre de cellules sensibles à la cachectine/TNF (facteur nécrosant des tumeurs), de stimuler la blastogénèse de thymocytes C3H/HeJ résistants aux endotoxines, ou d'induire la production de cachectine/TNF par des cellules primaires de macrophages de souris stimulées au thioglycolate.
- 45 42. Utilisation du produit selon la revendication 41, pour la préparation d'une composition pharmaceutique destinée au traitement de l'inflammation et/ou de la fièvre chez des mammifères, caractérisée en ce que ladite cytokine inflammatoire se fixe à l'héparine aux fortes concentrations salines et a tendance à former des agrégats de haut poids moléculaire d'une valeur supérieure à environ 10^6 Daltons dans des tampons à faible concentration saline.
- 50 43. Utilisation du produit selon la revendication 41, pour la préparation d'une composition pharmaceutique destinée

au traitement de l'inflammation et/ou de la fièvre chez des mammifères, dans laquelle ladite cytokine est capable d'induire la fièvre chez des lapins et d'induire la formation de superoxyde ou un stress oxydant dans des neutrophiles humains in vitro.

- 5 **44.** Utilisation du produit selon la revendication 41, pour la préparation d'une composition pharmaceutique destinée au traitement de l'inflammation et/ou de la fièvre chez des mammifères, dans laquelle ladite cytokine inflammatoire est susceptible d'être obtenue à partir de cellules animales qui ont pu être incubées avec un produit stimulant pouvant accompagner un stimulus invasif.
- 10 **45.** Utilisation du produit selon la revendication 41, pour la préparation d'une composition pharmaceutique destinée au traitement de l'inflammation et/ou de la fièvre chez des mammifères, dans laquelle ladite cytokine inflammatoire est obtenue à partir de cellules qui sont produites par réplication clonale.
- 15 **46.** Utilisation, pour la préparation d'une composition pharmaceutique pour prévenir l'inflammation et/ou la fièvre chez des mammifères, d'un produit choisi dans le groupe constitué par un anticorps dirigé contre une cytokine inflammatoire comprenant une protéine sous forme purifiée, un agent capable d'inhiber la production de ladite cytokine inflammatoire comprenant une protéine sous forme purifiée, un agent distinct d'un anticorps dirigé contre ladite cytokine inflammatoire comprenant une protéine sous forme purifiée capable d'être antagoniste de ladite cytokine inflammatoire ainsi que leurs mélanges, en une quantité efficace pour prévenir l'apparition de ladite inflammation et/ou de ladite fièvre, ladite cytokine inflammatoire comprenant une protéine sous forme purifiée qui est anionique dans des conditions physiologiques et présente un poids moléculaire apparent d'environ 8000 Daltons comme déterminé par SDS-PAGE et qui est apte à se fixer à l'héparine, induisant une inflammation localisée caractérisée par une infiltration de cellules polymorphonucléaires lorsqu'elle est administrée par la voie sous-cutanée et induisant une chimiocinésie de cellules polymorphonucléaires in vitro, tout en étant incapable de supprimer l'activité de l'enzyme anabolique lipoprotéine lipase, de présenter une cytotoxicité à l'encontre de cellules sensibles à la cachectine/TNF (facteur nécrosant des tumeurs), de stimuler la blastogénèse de thymocytes C3H/HeJ résistants aux endotoxines, ou d'induire la production de cachectine/TNF par des cellules primaires de macrophages de souris stimulées au thioglycolate.
- 20 **47.** Utilisation du produit selon la revendication 46, pour la préparation d'une composition pharmaceutique destinée à la prévention de l'inflammation et/ou de la fièvre chez des mammifères, dans laquelle ladite cytokine inflammatoire est anionique dans les conditions physiologiques et se fixe à l'héparine aux fortes concentrations salines et a tendance à former des agrégats de haut poids moléculaire d'une valeur supérieure à environ 10^6 Daltons dans des tampons à faible concentration saline.
- 30 **48.** Utilisation du produit selon la revendication 46, pour la préparation d'une composition pharmaceutique destinée à la prévention de l'inflammation et/ou de la fièvre chez des mammifères, dans laquelle ladite cytokine inflammatoire est capable d'induire la fièvre chez des lapins et d'induire la formation de superoxyde ou un stress oxydant dans des neutrophiles humains in vitro.
- 35 **49.** Utilisation du produit selon la revendication 46, pour la préparation d'une composition pharmaceutique destinée à la prévention de l'inflammation et/ou de la fièvre chez des mammifères, dans laquelle ladite cytokine inflammatoire est obtenue à partir de cellules qui sont produites par réplication clonale.
- 40 **50.** Utilisation du produit selon la revendication 46, pour la préparation d'une composition pharmaceutique destinée à la prévention de l'inflammation et/ou de la fièvre chez des mammifères, dans laquelle ladite cytokine inflammatoire est susceptible d'être obtenue à partir de cellules macrophages animales qui ont pu être incubées avec un produit stimulant pouvant accompagner un stimulus invasif.
- 45 **51.** Utilisation, pour la préparation d'une composition pharmaceutique destinée au traitement de maladies infectieuses et non infectieuses chez des mammifères, d'un produit choisi dans le groupe constitué par une cytokine inflammatoire comprenant une protéine sous forme purifiée, par un agent capable de favoriser la production et/ou l'activité de ladite cytokine inflammatoire comprenant une protéine sous forme purifiée, un agent capable de mimer l'activité de ladite cytokine inflammatoire comprenant une protéine sous forme purifiée, ainsi que leurs mélanges, ladite cytokine inflammatoire comprenant une protéine sous forme purifiée qui est anionique dans des conditions physiologiques et présente un poids moléculaire apparent d'environ 8000 Daltons comme déterminé par SDS-PAGE et qui est apte à se fixer à l'héparine, induisant une inflammation localisée caractérisée par une infiltration de cellules polymorphonucléaires lorsqu'elle est administrée par la voie sous-cutanée et induisant une chimiocinésie
- 50
- 55

de cellules polymorphonucléaires in vitro, tout en étant incapable de supprimer l'activité de l'enzyme anabolique lipoprotéine lipase, de présenter une cytotoxicité à l'encontre de cellules sensibles à la cachectine/TNF (facteur nécrosant des tumeurs), de stimuler la blastogénèse de thymocytes C3H/HeJ résistants aux endotoxines, ou d'induire la production de cachectine/TNF par des cellules primaires de macrophages de souris stimulées au thioglycolate.

5

52. Utilisation du produit selon la revendication 51, pour la préparation d'une composition pharmaceutique destinée au traitement de maladies infectieuses et non infectieuses chez des mammifères, dans laquelle ladite cytokine inflammatoire est anionique dans les conditions physiologiques et se fixe à l'héparine aux fortes concentrations salines et a tendance à former des agrégats de haut poids moléculaire d'une valeur supérieure à environ 10^6 Daltons dans des tampons à faible concentration saline.

10

53. Utilisation du produit selon la revendication 51, pour la préparation d'une composition pharmaceutique destinée au traitement de maladies infectieuses et non infectieuses chez des mammifères, dans laquelle ladite cytokine inflammatoire est capable d'induire la fièvre chez des lapins et d'induire la formation de superoxyde ou un stress oxydant dans des neutrophiles humains in vitro.

15

54. Utilisation du produit selon la revendication 51, pour la préparation d'une composition pharmaceutique destinée au traitement de maladies infectieuses et non infectieuses chez des mammifères, dans laquelle ladite cytokine inflammatoire est susceptible d'être obtenue à partir de cellules animales qui ont pu être incubées avec un produit stimulant pouvant accompagner un stimulus invasif.
